Gentry, Gorbunov, Halevi 2015 [GGH 15]

All based on **nonstandard** use of lattices

Obfuscation

Obfuscation:

- A compiler $P \rightarrow P^*$
- $P^* = P$ in functionality
- P^* is “unintelligible”, “hides information” in P

$P =$

`factorize()`

$P^* =$

```
XOpenDisplay( 0); z=RootWindow(e,0); for (XSetForeground(e,k=XCreateGC
(e,z,0,0),BlackPixel(e,0));
scanf("%lf%lf%lf",y +n,w+y, y+s)+1; y ++);
XSelectInput(e,z= XCreateSimpleWindow(e,z,0,0,400,400, 0,0,WhitePixel(e,0)
),KeyPressMask); for(XMapWindow(e,z); ; T=sin(O)){ struct timeval
```

Obfuscation

Obfuscation:

- A compiler $P \rightarrow P^*$
- $P^* = P$ in functionality
- P^* is “unintelligible”, “hides information” in P

Indistinguishability Obfuscation (iO):

- Defined by [Barak et al. 2001]
- Known to be the best-possible [Goldwasser, Rothblum 2007]
- First candidate (for general purpose obfuscation) based on multilinear maps [Garg et al. 2013]

Obfuscation

Obfuscation:

- A compiler $P \rightarrow P^*$
- $P^* = P$ in functionality
- P^* is “unintelligible”, “hides information” in P

Indistinguishability Obfuscation (iO):

- Defined by [Barak et al. 2001]
- Known to be the best-possible [Goldwasser, Rothblum 2007]
- First candidate (for general purpose obfuscation) based on multilinear maps [Garg et al. 2013]

Oversimplified idea:

- Decompose P into a, b, c, \dots (e.g. $P(x) = (ax + b)c$)
- Use **Multilinear maps** to encode $[a], [b], [c]$.
- Plus other mechanisms to prevent illegal evaluations.

Watermarking

Functional encryption

Indistinguishability obfuscation?
(if PCPRF is two-key secure)

How to build PCPRF?

🦄 Main construction [CC17]

Private constrained PRF for NC1 with 1-key security
from Learning With Errors.

Learning with errors [Regev 05]

$$Y = s \times A + E \pmod{q}$$

public matrix (coefficients)

secret vector

small amount of noise

LWE: given A , Y , find s .

Learning with errors [Regev 05]

$$Y = s \times A + E \pmod{q}$$

public matrix (coefficients)

secret vector

small amount of noise

LWE: given A , Y , find s .

Proved to be as hard as short-vector problems in lattices [Regev 05].
Conjectured to be hard even for quantum computers.

Starting point: a plain PRF by [Banerjee, Peikert, Rosen 12]

Starting point: a plain PRF by [Banerjee, Peikert, Rosen 12]

Key:

$$\begin{matrix} \boxed{s_{1,1}} & \boxed{s_{2,1}} & \dots & \boxed{s_{n,1}} \\ \boxed{s_{1,0}} & \boxed{s_{2,0}} & \dots & \boxed{s_{n,0}} \end{matrix} \quad \boxed{A} \quad \text{mod } q$$

Eval:

$$F(x) = \{ \prod s_{i,x_i} A \}_2$$

What we need in addition to build a PCPRF:

- + Embed **structures** in the secret terms to perform functionality
- + A proper **public mode** of the function

Step 1: Embed **structures**: permutation branching programs

Step 1: Embed **structures**: permutation branching programs

Key:

Step 2: Encode the structured key?

Step 2: Encode the structured key?

GGH15

Constrained Key:

A_1

$D_{1,1}$

$D_{2,1}$

...

$D_{n,1}$

$D_{1,0}$

$D_{2,0}$

...

$D_{n,0}$

Short explanation of the technical challenges

GGH15

Constrained Key:

A_1

$D_{1,1}$

$D_{2,1}$

...

$D_{n,1}$

$D_{1,0}$

$D_{2,0}$

...

$D_{n,0}$

Short explanation of the technical challenges

- GGH15 encoding uses LWE with **lattice trapdoors**, trapdoor sampling of arbitrary plaintext can be **dangerous** (as revealed by cryptanalytic attacks)

GGH15

Constrained Key:

A_1

Short explanation of the technical challenges

- GGH15 encoding uses LWE with **lattice trapdoors**, trapdoor sampling of arbitrary plaintext can be **dangerous** (as revealed by cryptanalytic attacks)
- [CC17] discovers a “**safe mode**” related to permutation matrices.

GGH15

Constrained Key:

A_1

Short explanation of the technical challenges

- GGH15 encoding uses LWE with **lattice trapdoors**, trapdoor sampling of arbitrary plaintext can be **dangerous** (as revealed by cryptanalytic attacks)
- [CC 17] discovers a “**safe mode**” related to permutation matrices.
- [CVW 18] shows “**more general safe modes**”. As a result, it improves the efficiency of e.g. private puncturable PRFs.

Demo: 2-bit PRF that is punctured on $x^*=11$:

[CC 17] uses
permutation matrices.

[CVW 18] uses diagonal
matrices (low-rank).

Performance?

Implementations of GGH15-based schemes:

1. BPobfus
2. PALISADE

Current status: (for 80-bit security)

| Multilinearity | generate the encodings | storage | time per evaluation |
|----------------|------------------------|---------|---------------------|
| 4 | 1 min | 1 GB | < 1 sec |
| 8 | 8 mins | 8 GB | < 4 sec |
| 16 | 120 mins | 300 GB | < 100 sec |

Performance?

Implementations of GGH15-based schemes:

1. BPobfus
2. PALISADE

Current status: (for 80-bit security)

| Multilinearity | generate the encodings | storage | time per evaluation |
|----------------|------------------------|---------|---------------------|
| 4 | 1 min | 1 GB | < 1 sec |
| 8 | 8 mins | 8 GB | < 4 sec |
| 16 | 120 mins | 300 GB | < 100 sec |

Estimation of 16 bit private puncturable PRF using [CVW 18]:
use multilinearity = 4, wordsize of $2^4 = 16$,

16 mins, 16 GB storage, 1 sec per eval.

Ran Canetti, Yilei Chen, Leonid Reyzin, Ron Rothblum
Eurocrypt 2018

A public function

$$h: \{0,1\}^l \rightarrow \{0,1\}^m$$

behaves like a random function?

One of the desirable property of a public random function is

Correlation Intractability

“infeasibility of finding ‘rare’ input-output relations”

Sparse Relations

*“For each input (x),
the fraction of outputs (y) in the relation is **negligible**”*

Sparse Relations

*“For each input (x) ,
the fraction of outputs (y) in the relation is **negligible**”*

Correlation intractability [Canetti, Goldreich, Halevi '98]

For all sparse relations R :

Adversary wins if $R(x, y)=1$

$H(????...?)=000000....XYZ3d83h$

$H(???...?) = 000000....XYZ3d83h$

$d \Rightarrow$ the best algorithm
shall run in time 2^d

Correlation intractability
for **moderately** sparse relations [CCRR 18]

How to construct?

What we know about CI:

[Canetti, Goldreich, Halevi 98] some parameters are impossible.

[Goldwasser, Kalai 03] more parameters are impossible.

[Bitanski et al. 13] Impossible to prove based on black-box reduction to efficiently falsifiable assumptions. (difficult to prove)

Before 2015: sometime cited as unconditionally impossible

What we know about CI:

...

SHA256 (and others) are heuristical candidates.

We want to base CI on clear mathematical problems.

Intuitive difficulty: how to handle “weird relations” like

$$R(x, y) = 1 \text{ iff the “2nd} \sim 2n\text{-th bits of } (3^x + x^2) = y$$

Canetti, Chen, Reyzin (TCC 2016-A)

Bounded correlation intractability from iO(Puncturable.PRF)

Canetti, Chen, Reyzin (TCC 2016-A)

Bounded correlation intractability from iO (Puncturable.PRF)

Canetti, Chen, Reyzin, Rothblum (Eurocrypt 2018)

CI for every sparse relation from exponentially KDM secure encryption schemes.

(with candidates from LWE and discrete-log like problems + KDM assumption)

Canetti, Chen, Reyzin (TCC 2016-A)

Bounded correlation intractability from iO(Puncturable.PRF)

Canetti, Chen, Reyzin, Rothblum (Eurocrypt 2018)

CI for every sparse relation from exponentially KDM secure encryption schemes.

(with candidates from LWE and discrete-log like problems + KDM assumption)

Main idea in the analysis:

1. Starting from a relation R and a random function F
2. Moving to F_R that is indistinguishable from F
3. Finally, argue the correlation intractability of F_R

Canetti, Chen, Reyzin (TCC 2016-A)

Bounded correlation intractability from iO(Puncturable.PRF)

Canetti, Chen, Reyzin, Rothblum (Eurocrypt 2018)

CI for every sparse relation from exponentially KDM secure encryption schemes.

(with candidates from LWE and discrete-log like problems + KDM assumption)

Main idea in the analysis:

1. Starting from a relation R and a random function F
2. Moving to F_R that is indistinguishable from F
3. Finally, argue the correlation intractability of F_R

Reasoning about moderate hardness is still an open problem.
