Today: A group with infeasible inversion was found in the volcano!

What is a group with infeasible inversion?

Hohenberger and Molnar (2003) propose groups with infeasible inversion Inversion is hard: given [ $x$ ], compute [ $-x$ ] is hard.

Composition is easy: given [ $x$ ], [ $y$ ], compute [ $x+y$ ] is easy.
Application: Directed transitive signature.
Another application: Broadcast encryption [ Irrer et al. 04 ].

They did not find out any group (representation) that satisfies this property.

A non-example: over a finite field $\mathrm{F}_{\mathrm{q}}:[\mathrm{a}]=\mathrm{g}^{\mathrm{a}} \bmod \mathrm{q}$
given $\mathrm{g}, \mathrm{g}^{\mathrm{a}}$, finding a is hard, but computing $\mathrm{g}^{-\mathrm{a}}$ is simple.

Attempts of constructing groups with infeasible inversion?

Attempt 1: Let G be the multiplicative group "in the exponent":

$$
\text { given } \mathrm{g}, \mathrm{~g}^{\mathrm{a}} \text {, compute } \mathrm{g}^{1 / a} \text { is hard in many groups. }
$$

But ... multiplication in the exponent is also hard, cannot compose.

Attempt 2: obfuscate the exponentiation function: Yes [ Yamakawa et al. 14 ]

$$
\text { encoding }(a)=\left\{g^{a}, \quad \operatorname{Obf}\{a, N\}(x)=x^{2 a} \bmod N\right\}
$$

Still, no candidate Gll was known without using general purpose obfuscation.

Today: Groups with infeasible inversion from hard problems on elliptic curve isogeny graphs defined over RSA moduli

## Road map

1. Elliptic curve isogenies can be represented by graphs like volcanoes.
2. Isogeny graphs can be used to represent a group.
3. Over finite fields, searching for close neighbors on the graph is easy.
4. Over an RSA modulus N , finding certain neighbors is hard.
5. Hardness of finding certain neighbors => hardness of inverting group elements.

## Elliptic curve 101

$$
E\left(F_{q}\right)=\left\{(x, y) \mid y^{2}=x^{3}+a x+b \text { over } F_{q}\right\} \cup\{O\}
$$

j-invariant of a curve: $j=1728 \cdot 4 a^{3} /\left(4 a^{3}+27 b^{2}\right)$
Over C, curves with the same j-invariant are isomorphic;
Over $\mathrm{F}_{\mathrm{q}}$ they are isomorphic, or the twist of each other.
In this talk let us treat curves with the same j-invariant as the same.

## Elliptic curve isogeny

Isogenous is an interesting equivalence relation between elliptic curves.
"A morphism $\phi$ from $E_{1}$ to $E_{2}$ is called an isogeny if it maps $O$ on $E_{1}$ to $O$ on $E_{2}$."

## Elliptic curve isogeny

Isogenous is an interesting equivalence relation between elliptic curves.
"A morphism $\Phi$ from $E_{1}$ to $E_{2}$ is called an isogeny if it maps $O$ on $E_{1}$ to $O$ on $E_{2}$."
[ Tate 1966 ] Two elliptic curves $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ over a finite field $\mathrm{F}_{\mathrm{q}}$ are isogenous iff they have the same number of points.

## Elliptic curve isogeny

Isogenous is an interesting equivalence relation between elliptic curves.
"A morphism $\phi$ from $E_{1}$ to $E_{2}$ is called an isogeny if it maps $O$ on $E_{1}$ to $O$ on $E_{2}$."
[ Tate 1966 ] Two elliptic curves $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ over a finite field $\mathrm{F}_{\mathrm{q}}$ are isogenous iff they have the same number of points.
[ Hasse 1933 ] The number of the points on $E\left(F_{q}\right):[q+1-2 \sqrt{ } q, q+1+2 \sqrt{ } q]$ [ Schoof 1985 ] given a, b and q, compute $\# \mathrm{E}\left(\mathrm{F}_{\mathrm{q}}\right)$ in time poly(log q).

## Elliptic curve isogeny

Isogenous is an interesting equivalence relation between elliptic curves.
"A morphism $\phi$ from $E_{1}$ to $E_{2}$ is called an isogeny if it maps $O$ on $E_{1}$ to $O$ on $E_{2}$."
[ Tate 1966 ] Two elliptic curves $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ over a finite field $\mathrm{F}_{\mathrm{q}}$ are isogenous iff they have the same number of points.
[ Hasse 1933] The number of the points on $E\left(F_{q}\right):[q+1-2 \sqrt{ } q, q+1+2 \sqrt{ } q$ ] [ Schoof 1985 ] given a, b and q, compute $\# \mathrm{E}\left(\mathrm{F}_{\mathrm{q}}\right)$ in time poly $(\log \mathrm{q})$.

An isogeny $\phi: E_{1} \rightarrow E_{2}$ can be explicitly written as a rational polynomial.

$$
\phi:(x, y)->\left(f(x) / h^{2}(x), g(x, y) / h^{3}(x)\right)
$$

The degree of an isogeny $\phi$ is the degree of the rational polynomial.

## Relation among isogenous curves - isogeny graph

Left: fix a degree L

$-\ell$-isogenies
-- $m$-isogenies

Right: the crater with multiple degrees

Isogeny graph: each vertex is an elliptic curve; each edge is an isogeny. The graph structure is described in the PhD Thesis of Kohel (1996).
The term "isogeny volcano" is introduced in [Fouquet, Morain 02].

## Representing the ideal class group

Left: fix a degree L

- $\ell$-isogenies
--- $m$-isogenies

Right: the crater with multiple degrees

The ideal class group $\mathrm{CL}(\mathrm{O})$ acts faithfully and transitively on the set

$$
\left.\operatorname{Ello}\left(\mathrm{F}_{\mathrm{q}}\right)=\{\mathrm{j}(\mathrm{E}): \mathrm{E} \text { with End}(\mathrm{E})=\mathrm{O}\} ; \quad \#\left|\mathrm{Ello}\left(\mathrm{~F}_{\mathrm{q}}\right)\right|=\mathrm{O}(\sqrt{\mathrm{q}})\right)
$$

Faithful: no group elements $g$ (except the identity) satisfies $g * x=x$ for all $x$ in $E l_{0}(F q)$.
Transitive: for all $x$, $y$ in $E l_{O}(F q)$, there is a $g$ in $C L(O)$ satisfies $g * x=y$.

## Example

$$
\begin{gathered}
j_{0}=15 \\
j_{6}=71
\end{gathered} \underbrace{j_{1}=48}_{j_{5}=55} j_{3}=29
$$

Example: a connecting component over $\mathrm{F}_{83}$, degree $\mathrm{L}=3$.

## Example

$$
\begin{gathered}
j_{5}=55 \\
j_{0}=15 \\
j_{6}=71
\end{gathered} j_{j_{4}=34}^{j_{1}=48} j_{3}=29
$$

Representing the class group $G=C L(D)$, with $D=-251, \#|G|=7$
Let jo represent the identity of G .
Let $j_{1}$ represents an element $a$ of norm 3 in $G$ (i.e. $a * E_{0}=E_{1}$ ), then $\mathrm{j}_{6}$ represents -a (i.e. $-\mathrm{a} * \mathrm{E}_{0}=\mathrm{E}_{6}$ )

## Road map

1. Elliptic curve isogenies can be represented by a graph.
2. Isogeny graphs can be used to represent a group.
3. Over finite fields, searching for close neighbors on the graph is easy.
4. Over an RSA modulus N, finding certain neighbors is hard.
5. Hardness of finding certain neighbors $=>$ hardness of inverting group elements

## Computational problems for isogeny over a finite field

Q1: Fix a polynomially large degree L , given a curve $\mathrm{E}_{0}$, is there a polynomial time algorithm that finds all of its L-isogenous neighbors?

## Computational problems for isogeny over a finite field

Q1: Fix a polynomially large degree L , given a curve $\mathrm{E}_{0}$, is there a polynomial time algorithm that finds all of its L-isogenous neighbors?

Answer: Yes. There are two ways.
(1) Use Velu's formulae
(2) Find (the j invariant of) E1 by solving modular polynomials,

## Modular polynomials

For all L>0, the L-th modular polynomial $\Psi_{\llcorner }$parameterizes pairs of elliptic curves related by an L-cyclic isogeny:
$\Psi_{\left\llcorner\left(j_{1}, j_{2}\right)\right.}=0$ if $j_{1}$ and $j_{2}$ are the $j_{\text {-invariants of } L \text {-isogenous elliptic curves. }}$
$\Psi_{\llcorner }(\mathrm{x}, \mathrm{y})$ has integer coefficients. Has degree $\mathrm{L}+1$ for prime L .

$$
j_{1}=48 \quad j_{2}=23
$$

In theory, $\Psi_{\mathrm{L}}$ is computable in polynomial time in L . In practice, the coefficients are very large.

$$
\begin{aligned}
& j_{0}=15 \\
& j_{6}=71
\end{aligned}
$$

## Computational problems for isogeny over a finite field

Q2: Randomly select two curves $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ from the graph, find an explicit isogeny between them.

Current status: conjectured to be hard, even for quantum computers.
[Couveignes 97], [Rostovtsev, Stolbunov 06]: post-quantum key-exchange SIDH [De Feo, Jao 11]

CSIDH [Castryck, Lange, Martindale, Panny, Renes 18]

## Road map

1. Elliptic curve isogenies can be represented by a graph.
2. Isogeny graphs can be used to represent a group.
3. Over finite fields, searching for close neighbors on the graph is easy.
4. Over an RSA modulus $N$, finding certain neighbors is hard.
5. Hardness of finding certain neighbors $=>$ hardness of inverting group elements

## Computational problems for isogeny over an RSA modulus $\mathbf{N}$

How to define an isogeny graph mod N :

1. The general case: $\mathrm{j}_{1}, \mathrm{j}_{2}$ are connected if $\Psi_{\llcorner }\left(\mathrm{j}_{1}, \mathrm{j}_{2}\right)=0 \bmod \mathrm{~N}$.
2. The special case: Assume the isogeny volcanoes over $F_{p}$ and $F_{q}$ have the same structure, then fix jo and a direction, take CRT.

Example: Representing G = CL( -251 ),

$$
j_{1}=48 \quad j_{2}=23
$$

$$
j_{5}=55^{j_{4}=34}
$$

$j_{1}=162{ }_{j 2}=36$

$$
j_{1}=760{ }_{j_{2}}=1766
$$

$j_{5}=116{ }^{j_{4}=134} \quad \overrightarrow{C R T}$

## Computational problems for isogeny over an RSA modulus $\mathbf{N}$

Basic neighbor search: Fix a poly degree L, given a curve $\mathrm{E}_{0}$ (its j-invariant mod N), is there a polynomial time algorithm that finds its L-isogenous neighbors?

Current status: seems to be hard.

## Computational problems for isogeny over an RSA modulus $\mathbf{N}$

Basic neighbor search: Fix a poly degree L, given a curve $\mathrm{E}_{0}$ (its j-invariant mod N), is there a polynomial time algorithm that finds its L-isogenous neighbors?

Current status: seems to be hard.

The two methods over the finite field don't work.

## Since they both require solving high degree polynomial mod N !

## Computational problems for isogeny over an RSA modulus $\mathbf{N}$

Joint-neighbor-search problem: Fix a degree L, given two curves $E_{0}, E_{1}$, find $E_{2}$ that is L -isogenous to $\mathrm{E}_{0}$, and $\mathrm{L}^{2}$-isogenous to $\mathrm{E}_{1}$ ?

Current status: also seems to be hard.

Natural attempt: take the gcd of $\Psi_{\mathrm{L}(\mathrm{j} 0, \mathrm{x})}$ and $\left.\Psi_{\mathrm{L}^{2}(\mathrm{j} 1}, \mathrm{x}\right)$,
 but the resulting polynomial has degree L , not 1 .

## Computational problems for isogeny over an RSA modulus $\mathbf{N}$

Joint-neighbor-search problem: Fix a degree L , given two curves $\mathrm{E}_{0}, \mathrm{E}_{1}$, find $\mathrm{E}_{2}$ that is L -isogenous to $\mathrm{E}_{0}$, and $\mathrm{L}^{2}$-isogenous to $\mathrm{E}_{1}$ ?

Current status: also seems to be hard.

- $\ell$-isogenies
--- $m$-isogenies

But for coprime degree joint neighbors,
gcd of $\Psi_{M}\left(\mathrm{j}_{1}, \mathrm{x}\right)$ and $\left.\Psi_{\llcorner(\mathrm{j} 2}, \mathrm{x}\right)$ gives a linear function
[Enge, Sutherland 10].

## Road map

1. Elliptic curve isogenies can be represented by a graph.
2. Isogeny graphs can be used to reprosent a group.
3. Over finite fields, searching for close neighbors on the graph is easy.
4. Over an RSA modulus N , finding certain neighbors is hard.
5. Hardness of finding certain neighbors => hardness of inverting group elements.

## Trapdoor group with infeasible inversion

Trapdoor: $p$, q, the discriminant D (which determines End( $\mathrm{E}_{0}$ )), invariants of $\mathrm{CL}(\mathrm{D})$
Public parameter: $\mathrm{N}=\mathrm{pq}$, $\mathrm{jo}=\mathrm{j}\left(\mathrm{E}_{0}\right)$
Encoding of an class group element a:
Canonical encoding of $a: j\left(E_{a}\right)$ such that $E_{a}=a * E_{0}$
Composable encoding of $\mathbf{a}$ : factorize $\mathbf{a}$ into poly-smooth ideals, publish the canonical encoding and the norm of each of them.

Infeasibility of inversion: (L, L²)-joint neighbor problem* Feasibility of composition*: when the norms of the ideals are coprime, then gcd of modular polys is linear.

## The difficulties in generating the parameters efficiently

Parameters: p, q, Eo s.t. End $\left(\mathrm{E}_{0} / \mathrm{F}_{\mathrm{p}}\right)=\operatorname{End}\left(\mathrm{E}_{0} / \mathrm{F}_{\mathrm{q}}\right)=\mathrm{O}$ of disc D.
Want D to be exponentially large (so that $\mathrm{CL}(\mathrm{D})$ is exponentially large).
Problem: how to find $\mathrm{E}_{0}, \mathrm{p}, \mathrm{q}$, with a given exponentially large discriminant D .
(The CM method only works when |D| is a polynomial, or $<10^{14}$ in practice)

Solution: Can let $D=\left(f_{1} \ldots f_{k}\right)^{2} \cdot D_{0}$ s.t. all the factors are poly
=> the order of $C L(\mathrm{D})$ is large but smooth, need to make sure the order is hidden.
=> Also need a short relation basis of $C L(D)$.
New Record: D with 154 digits [Beullens, Kleinjung, Vercauteren 19]

## Cryptanalysis attempts (more: Section 5 of the paper)

The attacker sees:
The modulus N , and a bunch of j -invariants of isogenous curves.
We conjecture that the attacker cannot get:

1. $p$ and $q$ such that $p q=N$
2. The number of points of $\mathrm{E}_{\mathrm{o}}\left(\mathrm{Z}_{\mathrm{N}}\right)$
3. The discriminant $D$
4. The group size of $C L(D)$

## Summary:

We propose a candidate trapdoor group with infeasible inversion from elliptic curve isogeny (available on eprint 2018/926).

Main assumption: (L, $L^{2}$ )-neighbor search problem on the isogeny graphs defined over RSA moduli

Applications of GII: broadcast encryption, directed transitive signatures, maybe more...
