

Recommendation Systems

Slides by: Anand Rajaraman, Jeffrey D. Ullman

From Scarcity to Abundance

- Shelf space is a scarce commodity for traditional retailers
 - Also: TV networks, movie theaters, ...
- The web enables near-zero-cost dissemination of information about products
 - From scarcity to abundance
- More choice necessitates better filters
 - Recommendation engines

Source: Chris Anderson (2004)

Sources: Erik Brynjolfsson and Jeffrey Hu, MIT, and Michael Smith, Carnegie Mellon; Barnes & Noble; Netflix; RealNetworks

Recommendation Types

- Editorial
- Simple aggregates
 - Top 10, Most Popular, Recent Uploads
- Tailored to individual users
 - Amazon, Netflix, ...

Formal Model

- C = set of Customers
- S = set of Items
- Utility function $u: C \times S \rightarrow R$
 - R = set of ratings
 - R is a totally ordered set
 - e.g., 0-5 stars, real number in $[0,1]$

Utility Matrix

King Kong

LOTR

Matrix

Nacho Libre

Alice

Key Problems

- Gathering “known” ratings for matrix
- Extrapolate unknown ratings from known ratings
 - Mainly interested in high unknown ratings
- Evaluating extrapolation methods

Gathering Ratings

- Explicit
 - Ask people to rate items
 - Doesn't work well in practice – people can't be bothered
- Implicit
 - Learn ratings from user actions
 - e.g., purchase implies high rating
 - What about low ratings?

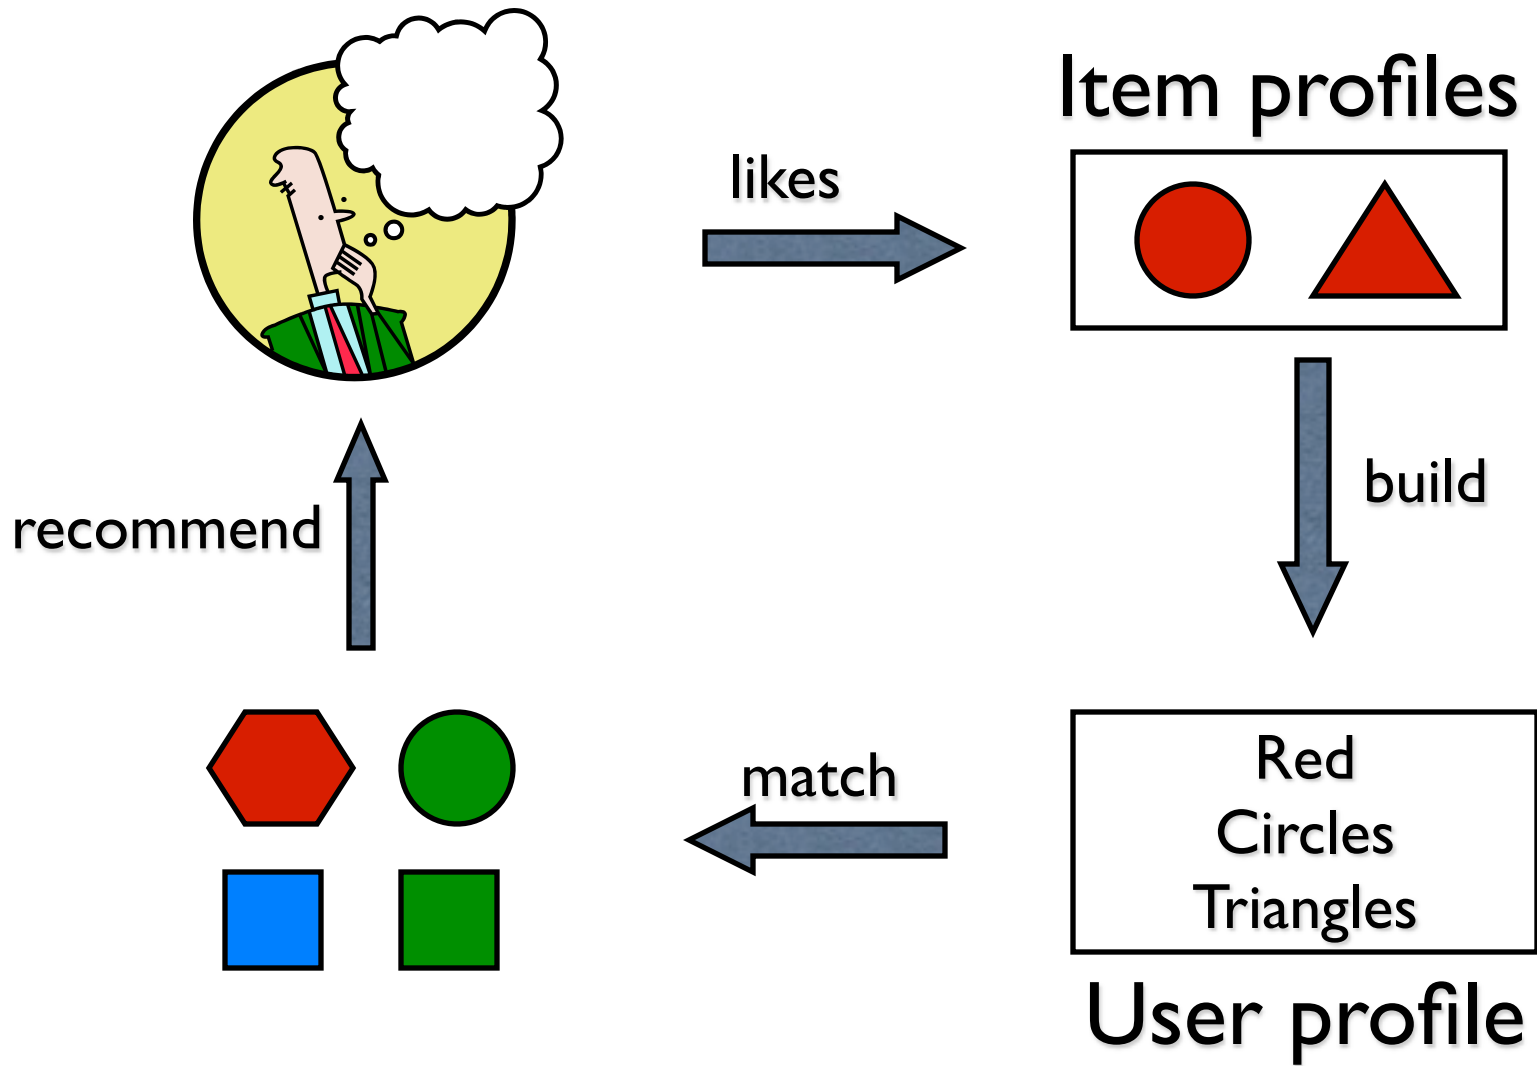

Extrapolating Utilities

- Key problem: matrix U is sparse
 - most people have not rated most items
- Three approaches
 - Content-based
 - Collaborative
 - Hybrid

Content-based recommendations

- Main idea: recommend items to customer C similar to previous items rated highly by C
- Movie recommendations
 - recommend movies with same actor(s), director, genre, ...
- Websites, blogs, news
 - recommend other sites with “similar” content

Plan of Action

Item Profiles

- For each item, create an **item profile**
- Profile is a set of features
 - movies: author, title, actor, director,...
 - text: set of “important” words in document
- How to pick important words?
 - Usual heuristic is TF.IDF (Term Frequency times Inverse Doc Frequency)

TF.IDF

f_{ij} = frequency of term t_i in document d_j

$$TF_{ij} = \frac{f_{ij}}{\max_k f_{kj}}$$

n_i = number of docs that mention term i

N = total number of docs

$$IDF_i = \log \frac{N}{n_i}$$

TF.IDF score $w_{ij} = TF_{ij} \times IDF_i$

Doc profile = set of words with highest TF.IDF scores, together with their scores

User profiles and prediction

- User profile possibilities:
 - Weighted average of rated item profiles
 - Variation: weight by difference from average rating for item ...
- Prediction heuristic
 - Given user profile \mathbf{c} and item profile \mathbf{s} , estimate $u(\mathbf{c}, \mathbf{s}) = \cos(\mathbf{c}, \mathbf{s}) = \mathbf{c} \cdot \mathbf{s} / (|\mathbf{c}| |\mathbf{s}|)$
 - Need efficient method to find items with high utility: later

Model-based approaches

- For each user, learn a classifier that classifies items into rating classes
 - liked by user and not liked by user
 - e.g., Bayesian,
- Apply classifier to each item to find recommendation candidates
- Problem: scalability -- will not investigate further

Limitations of content-based approach

- Finding the appropriate features
 - e.g., images, movies, music
- Overspecialization
 - Never recommends items outside user's content profile
 - People might have multiple interests
- Recommendations for new users
 - How to build a profile?

Collaborative filtering

- Consider user c
- Find set D of other users whose ratings are “similar” to c ’s ratings
- Estimate user’s ratings based on ratings of users in D

Similar Users

- Let r_x be the vector of user x 's ratings
- Cosine similarity measure
 - $\text{sim}(x, y) = \cos(r_x, r_y)$
- Pearson correlation coefficient

$$\text{sim}(x, y) = \frac{\sum_{s \in S_{xy}} (r_{xs} - \bar{r}_x)(r_{ys} - \bar{r}_y)}{\sqrt{\sum_{s \in S_{xy}} (r_{xs} - \bar{r}_x)^2 (r_{ys} - \bar{r}_y)^2}}$$

- S_{xy} = items rated by both users x and y

Complexity

- Expensive step is finding k most similar customers
 - $O(|U|)$
- Too expensive to do at runtime
 - Need to pre-compute
- Naïve precomputation takes time $O(N|U|)$
 - Simple trick gives some speedup
- Can use clustering, partitioning as alternatives, but quality degrades

Item-item collaborative filtering

- So far: User-user collaborative filtering
- Another view
 - For item s , find other similar items
 - Estimate rating for item based on ratings for similar items
 - Can use same similarity metrics and prediction functions as in user-user model
- In practice, it has been observed that item-item often works better than user-user

Pros and Cons of Collaborative Filtering

- Works for any kind of item
 - No feature selection needed
- New user problem
- New item problem
- Sparsity of rating matrix
 - Cluster-based smoothing?

Hybrid Methods

- Implement two separate recommenders and combine predictions
- Add content-based methods to collaborative filtering
 - item profiles for new item problem
 - demographics to deal with new user problem

Evaluating Predictions

- Compare predictions with known ratings
 - Root-mean-square error (RMSE)
- Another approach: 0/1 model
 - Coverage
 - Number of items/users for which system can make predictions
 - Precision
 - Accuracy of predictions
 - Receiver operating characteristic (ROC)
 - Tradeoff curve between false positives and false negatives

Problems with Measures

- Narrow focus on accuracy sometimes misses the point
 - Prediction Diversity
 - Prediction Context
 - Order of predictions
- In practice, we care only to predict high ratings
 - RMSE might penalize a method that does well for high ratings and badly for others

Add Data

- Leverage all the data
 - Don't try to reduce data size in an effort to make fancy algorithms work
 - Simple methods on large data do best
- Add more data
 - e.g., add IMDB data on genres
- More Data Beats Better Algorithms

Finding similar vectors

- Common problem that comes up in many settings
- Given a large number N of vectors in some high-dimensional space (M dimensions), find pairs of vectors that have high cosine-similarity
- e.g., user profiles, item profiles

Latent Factors

How can we compute matrices P and Q such that $R = P \times Q$

Computing Latent Factors

$$\min_{P, Q} \sum_{(i, j) \in R} (R(i, j) - P(i, :)Q(:, j))^2$$

- SVD could be used but we have **missing entries**
- Specialized methods!

Computing Latent Factors

$$\min_{P, Q} \sum_{(i, j) \in R} (R(i, j) - P(i, :)Q(:, j))^2$$

Computing Latent Factors

$$\min_{P, Q} \sum_{(i, j) \in R} (R(i, j) - P(i, :)Q(:, j))^2$$

- SVD:

$$\min_{V, \Sigma, U} \sum_{(i, j) \in R} (R(i, j) - (U\Sigma V^T)(i, j))^2$$

$$P = U \quad Q = \Sigma V^T$$

Dealing with missing entries

- **Want to:** minimize Sum Square Error (SSE) on unseen test data
- **Idea:** Minimize SSE on training data

$$\min_{P,Q} \sum_{(i,j) \text{ Training}} (R(i,j) - P(i,:)Q(:,j))^2 + \lambda \left(\sum_{i,j} P(i,j)^2 + \sum_{i,j} Q(i,j)^2 \right)$$
