Definitions of IND-CPA Security and Our Encryption Scheme

Symmetric Encryption Schemes

- Our treatment of symmetric encryption schemes is parameterized by three types:

```
type key. (* encryption keys, key_len bits *)
```

```
type text. (* plaintexts, text_len bits *)
```

```
type cipher. (* ciphertexts – scheme specific *)
```

- An encryption scheme is a *stateless* implementation of this module interface:

```
module type ENC = {
```

```
  proc key_gen() : key (* key generation *)
```

```
  proc enc(k : key, x : text) : cipher (* encryption *)
```

```
  proc dec(k : key, c : cipher) : text (* decryption *)
```

```
};
```

Encryption Oracles

- To define IND-CPA security of encryption schemes, we need the notion of an *encryption oracle*, which both the adversary and IND-CPA game will interact with:

```
module type E0 = {  
  (* initialization – generates key *)  
  proc * init() : unit  
  (* encryption by adversary before game's encryption *)  
  proc enc_pre(x : text) : cipher  
  (* one-time encryption by game *)  
  proc genc(x : text) : cipher  
  (* encryption by adversary after game's encryption *)  
  proc enc_post(x : text) : cipher  
}.
```

Standard Encryption Oracle

- Here is the standard encryption oracle, parameterized by an encryption scheme, **Enc**:

```
module Enc0 (Enc : ENC) : E0 = {  
  var key : key  
  var ctr_pre : int  
  var ctr_post : int  
  
  proc init() : unit = {  
    key <@ Enc.key_gen();  
    ctr_pre <- 0; ctr_post <- 0;  
  }  
}
```

Standard Encryption Oracle

```
proc enc_pre(x : text) : cipher = {  
  var c : cipher;  
  if (ctr_pre < limit_pre) {  
    ctr_pre <- ctr_pre + 1;  
    c <@ Enc.enc(key, x);  
  }  
  else {  
    c <- ciph_def; (* default result *)  
  }  
  return c;  
}
```

Standard Encryption Oracle

```
proc genc(x : text) : cipher = {  
  var c : cipher;  
  c <@ Enc.enc(key, x);  
  return c;  
}
```

Standard Encryption Oracle

```
proc enc_post(x : text) : cipher = {  
  var c : cipher;  
  if (ctr_post < limit_post) {  
    ctr_post <- ctr_post + 1;  
    c <@ Enc.enc(key, x);  
  }  
  else {  
    c <- ciph_def; (* default result *)  
  }  
  return c;  
}  
}.
```

Encryption Adversary

- An *encryption adversary* is parameterized by an encryption oracle:

```
module type ADV (E0 : E0) = {  
  (* choose a pair of plaintexts, x1/x2 *)  
  proc * choose() : text * text {E0.enc_pre}  
  
  (* given ciphertext c based on a random boolean b  
    (the encryption using E0.genc of x1 if b = true,  
    the encryption of x2 if b = false), try to guess b  
  *)  
  proc guess(c : cipher) : bool {E0.enc_post}  
}.
```

- Adversaries may be probabilistic.

IND-CPA Game

- The IND-CPA Game is parameterized by an encryption scheme and an encryption adversary:

```
module INDCPA (Enc : ENC, Adv : ADV) = {  
  module E0 = Enc0(Enc)           (* make E0 from Enc *)  
  module A = Adv(E0)             (* connect Adv to E0 *)  
  proc main() : bool = {  
    var b, b' : bool; var x1, x2 : text; var c : cipher;  
    E0.init();                    (* initialize E0 *)  
    (x1, x2) <@ A.choose();       (* let A choose x1/x2 *)  
    b <$ {0,1};                   (* choose boolean b *)  
    c <@ E0.genc(b ? x1 : x2);    (* encrypt x1 or x2 *)  
    b' <@ A.guess(c);            (* let A guess b from c *)  
    return b = b';              (* see if A won *)  
  }  
}
```

Pseudorandom Functions

- Our pseudorandom function (PRF) is an operator F with this type:

op $F : \text{key} \rightarrow \text{text} \rightarrow \text{text}.$

- We will assume that $d\text{text}$ ($d\text{key}$) is a sub-distribution on text (key) that is a distribution (is “lossless”), and where every element of text (key) has the same non-zero value:

op $d\text{text} : \text{text} \text{ distr}.$

op $d\text{key} : \text{key} \text{ distr}.$

Pseudorandom Functions

- A *random function* is a module with the following interface:

```
module type RF = {  
    (* initialization *)  
    proc * init() : unit  
    (* application to a text *)  
    proc f(x : text) : text  
};
```

Pseudorandom Functions

- Here is a random function made from our PRF **F**:

```
module PRF : RF = {  
  var key : key  
  proc init() : unit = {  
    key <$ dkey;  
  }  
  proc f(x : text) : text = {  
    var y : text;  
    y <- F key x;  
    return y;  
  }  
}.
```

Pseudorandom Functions

- Here is a random function made from true randomness:

```
module TRF : RF = {
  (* mp is a finite map associating texts with texts *)
  var mp : (text, text) fmap
  proc init() : unit = {
    mp <- empty; (* empty map *)
  }
  proc f(x : text) : text = {
    var y : text;
    if (! x \in mp) { (* give x a random value in *)
      y <$ dtext; (* mp if not already in mp's domain *)
      mp.[x] <- y;
    }
    return oget mp.[x]; (* return value of x in mp *)
  }
}.
```

Pseudorandom Functions

- A *random function adversary* is parameterized by a random function module:

```
module type RFA (RF : RF) = {  
  proc * main() : bool {RF.f}  
};
```

- Here is the random function game:

```
module GRF (RF : RF, RFA : RFA) = {  
  module A = RFA(RF)  
  proc main() : bool = {  
    var b : bool;  
    RF.init();  
    b <@ A.main();  
    return b;  
  }  
};
```

Pseudorandom Functions

- Our PRF F is “good” if and only if the following is small, whenever RFA is limited in the amount of computation it may do (maybe we say it runs in polynomial time):

$$\left| \Pr[\text{GRF}(\text{PRF}, \text{RFA}).\text{main}() \text{ @ } \&m : \text{res}] - \Pr[\text{GRF}(\text{TRF}, \text{RFA}).\text{main}() \text{ @ } \&m : \text{res}] \right|$$

Our Symmetric Encryption Scheme

- We construct our encryption scheme **Enc** out of **F**:

`(+^)` : text \rightarrow text \rightarrow text (* bitwise exclusive or *)

`type cipher = text * text.` (* ciphertexts *)

```
module Enc : ENC = {  
  proc key_gen() : key = {  
    var k : key;  
    k <$ dkey;  
    return k;  
  }  
}
```

Our Symmetric Encryption Scheme

```
proc enc(k : key, x : text) : cipher = {  
  var u : text;  
  u <$ dtext;  
  return (u, x +^ F k u);  
}
```

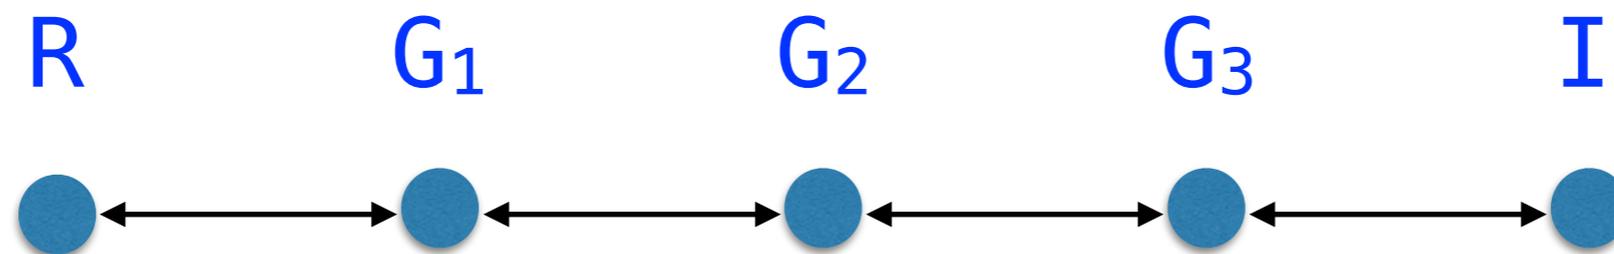

```
proc dec(k : key, c : cipher) : text = {  
  var u, v : text;  
  (u, v) <- c;  
  return v +^ F k u;  
}
```

```
};
```

Sequence of Games Approach

- Our proof of IND-CPA security uses the *sequence of games approach*, which is used to connect a “real” game **R** with an “ideal” game **I** via a sequence of intermediate games.
- Each of these games is parameterized by the adversary, and each game has a **main** procedure returning a boolean.
- We want to establish an upper bound for

$$\left| \Pr[\mathbf{R}.\text{main}() @ \mathfrak{m} : \text{res}] - \Pr[\mathbf{I}.\text{main}() : \text{res}] \right|$$

Sequence of Games Approach

- Suppose we can prove

$$\text{` | Pr}[R.\text{main}() \text{ @ } \&m : \text{res}] - \text{Pr}[G_1.\text{main}() : \text{res}] \text{ | } \leq b_1$$

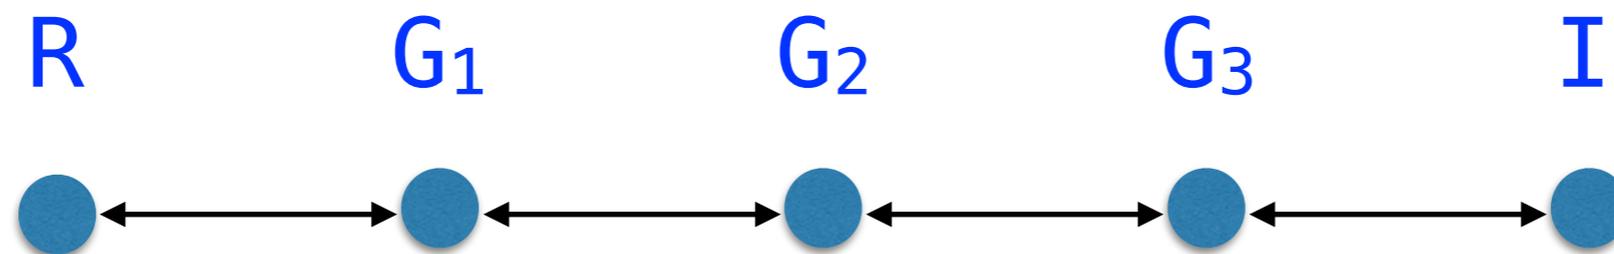

$$\text{` | Pr}[G_1.\text{main}() \text{ @ } \&m : \text{res}] - \text{Pr}[G_2.\text{main}() : \text{res}] \text{ | } \leq b_2$$

$$\text{` | Pr}[G_2.\text{main}() \text{ @ } \&m : \text{res}] - \text{Pr}[G_3.\text{main}() : \text{res}] \text{ | } \leq b_3$$

$$\text{` | Pr}[G_3.\text{main}() \text{ @ } \&m : \text{res}] - \text{Pr}[I.\text{main}() : \text{res}] \text{ | } \leq b_4$$

for some b_1 , b_2 , b_3 and b_4 . Then we can conclude

$$\text{` | Pr}[R.\text{main}() \text{ @ } \&m : \text{res}] - \text{Pr}[I.\text{main}() \text{ @ } \&m : \text{res}] \text{ | } \leq b_1 + b_2 + b_3 + b_4$$

Sequence of Games Approach

- To establish an upper bound for

$$\left| \Pr[\text{INDCPA}(\text{Enc}, \text{Adv}).\text{main}() @ \epsilon : \text{res}] - 1/2 \right|,$$

we can use a sequence of games to connect **INDCPA(Enc, Adv)** to an ideal game **I** such that

$$\Pr[\text{I}.\text{main}() @ \epsilon : \text{res}] = 1/2.$$

- The overall upper bound will be the sum $b_1 + \dots + b_n$ of the sequence b_1, \dots, b_n of upper bounds of the steps of the sequence of games.
- We start with **INDCPA(Enc, Adv)** and make a sequence of simplifications, hoping to get to such an **I**.

Starting the Proof in a Section

- First, we enter a “section”, and declare our adversary **Adv** as not interfering with certain modules and as being lossless:

`section.`

```
declare module Adv : ADV{Enc0, PRF, TRF, Adv2RFA}.
```

```
axiom Adv_choose_ll :
```

```
  forall (E0 <: E0{Adv}),
```

```
  islossless E0.enc_pre => islossless Adv(E0).choose.
```

```
axiom Adv_guess_ll :
```

```
  forall (E0 <: E0{Adv}),
```

```
  islossless E0.enc_post => islossless Adv(E0).guess.
```

From the
Previous Class

Step 1: Replacing PRF with TRF

- In our first step, we switch to using a true random function instead of a pseudorandom function in our encryption scheme.
- When doing this, we inline the encryption scheme into a new kind of encryption oracle, **E0_RF**, which is parameterized by a random function.
- We also instrument **E0_RF** to detect two kinds of “clashes” (repetitions) in the generation of the inputs to the random function.
 - This is in preparation for Steps 2 and 3.

Step 1: Replacing PRF with TRF

```
local module EO_RF (RF : RF) : EO = {  
  var ctr_pre : int  
  var ctr_post : int  
  var inps_pre : text fset  
  var clash_pre : bool  
  var clash_post : bool  
  var genc_inp : text  
  
  proc init() = {  
    RF.init();  
    ctr_pre <- 0; ctr_post <- 0; inps_pre <- fset0;  
    clash_pre <- false; clash_post <- false;  
    genc_inp <- text0;  
  }  
}
```

Step 1: Replacing PRF with TRF

```
proc enc_pre(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  if (ctr_pre < limit_pre) {  
    ctr_pre <- ctr_pre + 1;  
    u <$ dtext;  
    inps_pre <- inps_pre `|` fset1 u;  
    v <@ RF.f(u);  
    c <- (u, x +^ v);  
  }  
  else {  
    c <- (text0, text0);  
  }  
  return c;  
}
```

size of `inps_pre`
is at most `limit_pre`

Step 1: Replacing PRF with TRF

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  if (mem inps_pre u) {  
    clash_pre <- true;  
  }  
  genc_inp <- u;  
  v <@ RF.f(u);  
  c <- (u, x +^ v);  
  return c;  
}
```

Step 1: Replacing PRF with TRF

```
proc enc_post(x : text) : cipher = {
  var u, v : text; var c : cipher;
  if (ctr_post < limit_post) {
    ctr_post <- ctr_post + 1;
    u <$ dtext;
    if (u = genc_inp) {
      clash_post <- true;
    }
    v <@ RF.f(u);
    c <- (u, x +^ v);
  }
  else {
    c <- (text0, text0);
  }
  return c;
}
}.
```

Step 1: Replacing PRF with TRF

- Now, we define a game **G1** using **E0_RF**:

```
local module G1 (RF : RF) = {
  module E = E0_RF(RF)
  module A = Adv(E)

  proc main() : bool = {
    var b, b' : bool; var x1, x2 : text; var c : cipher;
    E.init();
    (x1, x2) <@ A.choose();
    b <$ {0,1};
    c <@ E.genc(b ? x1 : x2);
    b' <@ A.guess(c);
    return b = b';
  }
}.
```

Step 1: Replacing PRF with TRF

- Then it is easy to prove:

```
local lemma INDCPA_G1_PRF &m :  
  Pr[INDCPA(Enc, Adv).main() @ &m : res] =  
  Pr[G1(PRF).main() @ &m : res].
```

- To upper-bound

```
` | Pr[G1(PRF).main() @ &m : res] -  
  Pr[G1(TRF).main() @ &m : res] |,
```

we need to construct a module `Adv2RFA` that transforms `Adv` into a random function adversary:

```
module Adv2RFA(Adv : ADV, RF : RF) = {  
  ...  
  proc main() : bool = { ... }  
}.
```

`Adv2RFA(Adv)`
is a random
function
adversary

Step 1: Replacing PRF with TRF

- Our goal in defining **Adv2RFA** is for this lemma to be provable:

```
local lemma G1_GRF (RF <: RF{E0_RF, Adv, Adv2RFA}) &m :  
  Pr[G1(RF).main() @ &m : res] =  
  Pr[GRF(RF, Adv2RFA(Adv)).main() @ &m : res].
```

- Recall the definition of **GRF**:

```
module GRF (RF : RF, RFA : RFA) = {  
  module A = RFA(RF)  
  proc main() : bool = {  
    var b : bool;  
    RF.init();  
    b <@ A.main();  
    return b;  
  }  
}.
```

Step 1: Replacing PRF with TRF

```
module Adv2RFA(Adv : ADV, RF : RF) = {  
  module E0 : E0 = { (* uses RF *)  
    var ctr_pre : int  
    var ctr_post : int  
  
    proc init() : unit = {  
      (* RF.init will be called by GRF *)  
      ctr_pre <- 0; ctr_post <- 0;  
    }  
  }  
}
```

Step 1: Replacing PRF with TRF

```
proc enc_pre(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  if (ctr_pre < limit_pre) {  
    ctr_pre <- ctr_pre + 1;  
    u <$ dtext;  
    v <@ RF.f(u);  
    c <- (u, x + ^ v);  
  }  
  else {  
    c <- (text0, text0);  
  }  
  return c;  
}
```

identical to
EO_RF

Step 1: Replacing PRF with TRF

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  v <@ RF.f(u);  
  c <- (u, x +^ v);  
  return c;  
}
```

identical to
EO_RF

Step 1: Replacing PRF with TRF

```
proc enc_post(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  if (ctr_post < limit_post) {  
    ctr_post <- ctr_post + 1;  
    u <$ dtext;  
    v <@ RF.f(u);  
    c <- (u, x +^ v);  
  }  
  else {  
    c <- (text0, text0);  
  }  
  return c;  
}
```

identical to
EO_RF

Step 1: Replacing PRF with TRF

```
module A = Adv(E0)

proc main() : bool = {
  var b, b' : bool; var x1, x2 : text; var c : cipher;
  E0.init();
  (x1, x2) <@ A.choose();
  b <$ {0,1};
  c <@ E0.genc(b ? x1 : x2);
  b' <@ A.guess(c);
  return b = b';
}
}.
```

Like **G1**, except **Adv**
and **main** use **E0**
instead of **Enc0(RF)**

Step 1: Replacing PRF with TRF

- From

```
local lemma G1_GRF (RF <: RF{E0_RF, Adv, Adv2RFA}) &m :  
  Pr[G1(RF).main() @ &m : res] =  
  Pr[GRF(RF, Adv2RFA(Adv)).main() @ &m : res].
```

we can conclude

```
Pr[INDCPA(Enc, Adv).main() @ &m : res] =  
Pr[G1(PRF).main() @ &m : res] =  
Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res]
```

and

```
Pr[G1(TRF).main() @ &m : res] =  
Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]
```

Step 1: Replacing PRF with TRF

- Thus

local lemma INDCPA_G1_TRF &m :

` |Pr[INDCPA(Enc, Adv).main() @ &m : res] -

Pr[G1(TRF).main() @ &m : res]| =

` |Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res] -

Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]|.

- Here, we have an exact upper bound.

Step 2: Oblivious Update in **genc**

- In Step 2, we make use of **up to bad reasoning**, to transition to a game in which the encryption oracle, **E0_0**, uses a true random function and “obliviously” (“O” for “oblivious”) updates the true random function’s map — i.e., overwrites what may already be stored in the map.

Step 2: Oblivious Update in `genc`

```
local module E0_0 : E0 = {  
  var ctr_pre : int  
  var ctr_post : int  
  var clash_pre : bool  
  var clash_post : bool  
  var genc_inp : text
```

don't need `inps_pre` —
can use `TRF.mp`'s domain

```
proc init() = {  
  TRF.init();  
  ctr_pre <- 0; ctr_post <- 0; clash_pre <- false;  
  clash_post <- false; genc_inp <- text0;  
}
```

Step 2: Oblivious Update in `genc`

```
proc enc_pre(x : text) : cipher = {
  var u, v : text; var c : cipher;
  if (ctr_pre < limit_pre) {
    ctr_pre <- ctr_pre + 1;
    u <$ dtext;
    v <@ TRF.f(u);
    c <- (u, x +^ v);
  }
  else {
    c <- (text0, text0);
  }
  return c;
}
```

size of domain of `TRF.mp`
is at most `limit_pre`

Step 2: Oblivious Update in `genc`

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  if (u \in TRF.mp) {  
    clash_pre <- true;  
  }  
  genc_inp <- u;  
  v <$ dtext;  
  TRF.mp.[u] <- v;  
  c <- (u, x +^ v);  
  return c;  
}
```

can now use
`TRF.mp`'s domain

Step 2: Oblivious Update in `genc`

```
proc enc_post(x : text) : cipher = {
  var u, v : text; var c : cipher;
  if (ctr_post < limit_post) {
    ctr_post <- ctr_post + 1;
    u <$ dtext;
    if (u = genc_inp) {
      clash_post <- true;
    }
    v <@ TRF.f(u);
    c <- (u, x +^ v);
  }
  else {
    c <- (text0, text0);
  }
  return c;
}
```

Step 2: Oblivious Update in `genc`

```
local module G2 = {
  module A = Adv(E0_0)

  proc main() : bool = {
    var b, b' : bool; var x1, x2 : text; var c : cipher;
    E0_0.init();
    (x1, x2) <@ A.choose();
    b <$ {0,1};
    c <@ E0_0.genc(b ? x1 : x2);
    b' <@ A.guess(c);
    return b = b';
  }
}.
```

Step 2: Oblivious Update in `genc`

```
local lemma G1_TRF_G2_main :
  equiv
  [G1(TRF).main ~ G2.main :
    true ==>
    ={clash_pre}(E0_RF, E0_0) /\
    (! E0_RF.clash_pre{1} => ={res})].

local lemma G2_main_clash_ub &m :
  Pr[G2.main() @ &m : E0_0.clash_pre] <=
  limit_pre%r / (2 ^ text_len)%r.

local lemma G1_TRF_G2 &m :
  `|Pr[G1(TRF).main() @ &m : res] -
  Pr[G2.main() @ &m : res]| <=
  limit_pre%r / (2 ^ text_len)%r.
```

Step 2: Oblivious Update in `genc`

- Then we can use the triangular inequality to summarize:

```
local lemma INDCPA_G2 &m :  
  `|Pr[INDCPA(Enc, Adv).main() @ &m : res] -  
    Pr[G2.main() @ &m : res]| <=  
  `|Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res] -  
    Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]| +  
  limit_pre%r / (2 ^ text_len)%r.
```

New Material

Step 3: Independent Choice in `genc`

- In Step 3, we again make use of up to bad reasoning, this time transitioning to a game in which the encryption oracle, `E0_I`, chooses the text value to be exclusive or-ed with the plaintext in a way that is “independent” (“I” for “independent”) from the true random function’s map, i.e., without updating that map.
- We no longer need to detect “pre” clashes (clashes in `genc` with a `u` chosen in a call to `enc_pre`).

Step 3: Independent Choice in `genc`

```
local module E0_I : E0 = {  
  var ctr_pre : int  
  var ctr_post : int  
  var clash_post : bool  
  var genc_inp : text  
  
  proc init() = {  
    TRF.init();  
    ctr_pre <- 0; ctr_post <- 0;  
    clash_post <- false; genc_inp <- text0;  
  }  
}
```

no longer need
`clash_pre`

Step 3: Independent Choice in `genc`

```
proc enc_pre(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  if (ctr_pre < limit_pre) {  
    ctr_pre <- ctr_pre + 1;  
    u <$ dtext;  
    v <@ TRF.f(u);  
    c <- (u, x +^ v);  
  }  
  else {  
    c <- (text0, text0);  
  }  
  return c;  
}
```

no changes
from `E0_0`

Step 3: Independent Choice in `genc`

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  genc_inp <- u;  
  v <$ dtext;  
  (* removed: TRF.mp.[u] <- v; *)  
  c <- (u, x +^ v);  
  return c;  
}
```

Step 3: Independent Choice in `genc`

```
proc enc_post(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  if (ctr_post < limit_post) {  
    ctr_post <- ctr_post + 1;  
    u <$ dtext;  
    if (u = genc_inp) {  
      clash_post <- true;  
    }  
    v <@ TRF.f(u);  
    c <- (u, x +^ v);  
  }  
  else {  
    c <- (text0, text0);  
  }  
  return c;  
}  
}
```

no changes
from `E0_0`

Step 3: Independent Choice in `genc`

```
local module G3 = {
  module A = Adv(E0_I)

  proc main() : bool = {
    var b, b' : bool; var x1, x2 : text; var c : cipher;
    E0_I.init();
    (x1, x2) <@ A.choose();
    b <$ {0,1};
    c <@ E0_I.genc(b ? x1 : x2);
    b' <@ A.guess(c);
    return b = b';
  }
}.
```

Step 3: Independent Choice in `genc`

```
local lemma G2_G3_main :  
  equiv  
  [G2.main ~ G3.main :  
   true ==>  
   ={clash_post}(E0_0, E0_I) /\  
   (! E0_0.clash_post{1} => ={res})].
```

- The subtle issue with this proof is that after the calls to `E0_0.genc` / `E0_I.genc` the maps will almost certainly give different values to `genc_inp` — but if `clash_post` doesn't get set, that won't matter.
- Because the up to bad reasoning involves `Adv`'s `guess` procedure (which uses `enc_post`), we need that `guess` is lossless.

Step 3: Independent Choice in `genc`

```
local lemma G3_main_clash_ub &m :  
  Pr[G3.main() @ &m : E0_I.clash_post] <=  
  limit_post%r / (2 ^ text_len)%r.
```

- This is proved using the `fel` (failure event lemma) tactic, which lets us upper-bound the probability that calling `Adv.guess` (which calls `E0_I.enc_post`) will cause `E0_I.clash_post` to be set.
 - Until the limit `limit_post` is exceeded, each call of `E0_I.enc_post` has a $1\%r / (2 \wedge \text{text_len})\%r$ chance of generating an input `u` to the true random function that clashes with `genc_inp`, and so of setting `E0_I.clash_post`.

Step 3: Independent Choice in **genc**

```
local lemma G2_G3 &m :  
  `|Pr[G2.main() @ &m : res] -  
    Pr[G3.main() @ &m : res]| <=  
  limit_post%r / (2 ^ text_len)%r.
```

```
local lemma INDCPA_G3 &m :  
  `|Pr[INDCPA(Enc, Adv).main() @ &m : res] -  
    Pr[G3.main() @ &m : res]| <=  
  `|Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res] -  
    Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]| +  
  limit_pre%r / (2 ^ text_len)%r +  
  limit_post%r / (2 ^ text_len)%r.
```

Step 3: Independent Choice in **genc**

```
local lemma G2_G3 &m :  
  `|Pr[G2.main() @ &m : res] -  
    Pr[G3.main() @ &m : res]| <=  
  limit_post%r / (2 ^ text_len)%r.
```

```
local lemma INDCPA_G3 &m :  
  `|Pr[INDCPA(Enc, Adv).main() @ &m : res] -  
    Pr[G3.main() @ &m : res]| <=  
  `|Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res] -  
    Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]| +  
  (limit_pre%r + limit_post%r) / (2 ^ text_len)%r.
```

Step 4: One-time Pad Argument

- In Step 4, we can switch to an encryption oracle `E0_N` in which the right side of the ciphertext produced by `E0_N.genc` makes no (“N” for “no”) reference to the plaintext.
- We no longer need any instrumentation for detecting clashes.

Step 4: One-time Pad Argument

```
local module E0_N : E0 = {  
  var ctr_pre : int  
  var ctr_post : int  
  
  proc init() = {  
    TRF.init();  
    ctr_pre <- 0; ctr_post <- 0;  
  }  
}
```

Step 4: One-time Pad Argument

```
proc enc_pre(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  if (ctr_pre < limit_pre) {  
    ctr_pre <- ctr_pre + 1;  
    u <$ dtext;  
    v <@ TRF.f(u);  
    c <- (u, x +^ v);  
  }  
  else {  
    c <- (text0, text0);  
  }  
  return c;  
}
```

Step 4: One-time Pad Argument

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  v <$ dtext;  
  c <- (u, v);  
  return c;  
}
```

c is
independent
from **x**

Step 4: One-time Pad Argument

```
proc enc_post(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  if (ctr_post < limit_post) {  
    ctr_post <- ctr_post + 1;  
    u <$ dtext;  
    v <@ TRF.f(u);  
    c <- (u, x +^ v);  
  }  
  else {  
    c <- (text0, text0);  
  }  
  return c;  
}  
}.
```

Step 4: One-time Pad Argument

```
local module G4 = {  
  module A = Adv(E0_N)  
  
  proc main() : bool = {  
    var b, b' : bool; var x1, x2 : text; var c : cipher;  
    E0_N.init();  
    (x1, x2) <@ A.choose();  
    b <$ {0,1};  
    c <@ E0_N.genc(text0);  
    b' <@ A.guess(c);  
    return b = b';  
  }  
}.
```

what is
different,
here?

Step 4: One-time Pad Argument

```
local module G4 = {
  module A = Adv(E0_N)

  proc main() : bool = {
    var b, b' : bool; var x1, x2 : text; var c : cipher;
    E0_N.init();
    (x1, x2) <@ A.choose();
    b <$ {0,1};
    c <@ E0_N.genc(text0);
    b' <@ A.guess(c);
    return b = b';
  }
}.
```

argument to
genc is
irrelevant

Step 4: One-time Pad Argument

- When proving

```
local lemma E0_I_E0_N_genc :  
  equiv[E0_I.genc ~ E0_N.genc :  
    true ==> ={res}].
```

we apply a standard one-time pad use of the `rnd` tactic to show that

```
v <$ dtext;  
c <- (u, x +^ v);
```

is equivalent to

```
v <$ dtext;  
c <- (u, v);
```

Step 4: One-time Pad Argument

```
local lemma G3_G4 &m :  
  Pr[G3.main() @ &m : res] = Pr[G4.main() @ &m : res].
```

```
local lemma INDCPA_G4 &m :  
  `|Pr[INDCPA(Enc, Adv).main() @ &m : res] -  
    Pr[G4.main() @ &m : res]| <=  
  `|Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res] -  
    Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]| +  
  (limit_pre%r + limit_post%r) / (2 ^ text_len)%r.
```

Step 5: Proving **G4**'s Probability

- When proving

```
local lemma G4_prob &m :  
  Pr[G4.main() @ &m : res] = 1%r / 2%r.
```

we can reorder

```
b <$ {0,1};  
c <@ E0_N.genc(text0);  
b' <@ A.guess(c);  
return b = b';
```

to

```
c <@ E0_N.genc(text0);  
b' <@ A.guess(c);  
b <$ {0,1};  
return b = b';
```

- We use that **Adv**'s procedures are lossless.

IND-CPA Security Result

Lemma $\text{INDCPA}' \ \&m$:

$$\begin{aligned} & \left| \Pr[\text{INDCPA}(\text{Enc}, \text{Adv}).\text{main}() \ @ \ \&m : \text{res}] - \right. \\ & \quad \left. \frac{1}{2} \right| \leq \\ & \left| \Pr[\text{GRF}(\text{PRF}, \text{Adv2RFA}(\text{Adv})).\text{main}() \ @ \ \&m : \text{res}] - \right. \\ & \quad \left. \Pr[\text{GRF}(\text{TRF}, \text{Adv2RFA}(\text{Adv})).\text{main}() \ @ \ \&m : \text{res}] \right| + \\ & \quad (\text{limit_pre} + \text{limit_post}) / (2^{\text{text_len}}). \end{aligned}$$

end section.

- When we exit the section, the universal quantification of Adv , and the assumptions that its procedures are lossless are automatically added to INDCPA' . By moving the quantification over $\&m$ to before the losslessness assumptions, we get our security result:

IND-CPA Security Result

Lemma INDCPA ($Adv \leq ADV\{Enc0, PRF, TRF, Adv2RFA\}$) $\&m :$
(forall ($E0 \leq E0\{Adv\}$),
islossless $E0.enc_pre \Rightarrow islossless Adv(E0).choose \Rightarrow$
(forall ($E0 \leq E0\{Adv\}$),
islossless $E0.enc_post \Rightarrow islossless Adv(E0).guess \Rightarrow$
`|Pr[INDCPA(Enc, Adv).main() @ $\&m : res]$ -
1%r / 2%r| \leq
`|Pr[GRF(PRF, Adv2RFA(Adv)).main() @ $\&m : res]$ -
Pr[GRF(TRF, Adv2RFA(Adv)).main() @ $\&m : res]$ | +
(limit_pre%r + limit_post%r) / (2 ^ text_len)%r.

- Q: How small is this upper bound?
- A: We can make assumptions about the efficiency of Adv (and inspect $Adv2RFA$ to see it too is efficient), and we can tune $limit_pre$, $limit_post$ and $text_len$.

IND-CPA Security Result

```
lemma INDCPA (Adv <: ADV{Enc0, PRF, TRF, Adv2RFA}) &m :
  (forall (E0 <: E0{Adv}),
    islossless E0.enc_pre => islossless Adv(E0).choose) =>
  (forall (E0 <: E0{Adv}),
    islossless E0.enc_post => islossless Adv(E0).guess) =>
  `|Pr[INDCPA(Enc, Adv).main() @ &m : res] -
    1%r / 2%r| <=
  `|Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res] -
    Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]| +
  (limit_pre%r + limit_post%r) / (2 ^ text_len)%r.
```

- Q: If we remove the restriction on **Adv** (**{Enc0, PRF, TRF, Adv2RFA}**), what would happen?
- A: Various tactic applications would fail; e.g., calls to the **Adv**'s procedures, as they could invalidate assumptions.

IND-CPA Security Result

```
lemma INDCPA (Adv <: ADV{Enc0, PRF, TRF, Adv2RFA}) &m :
  (forall (E0 <: E0{Adv}),
    islossless E0.enc_pre => islossless Adv(E0).choose) =>
  (forall (E0 <: E0{Adv}),
    islossless E0.enc_post => islossless Adv(E0).guess) =>
  `|Pr[INDCPA(Enc, Adv).main() @ &m : res] -
    1%r / 2%r| <=
  `|Pr[GRF(PRF, Adv2RFA(Adv)).main() @ &m : res] -
    Pr[GRF(TRF, Adv2RFA(Adv)).main() @ &m : res]| +
  (limit_pre%r + limit_post%r) / (2 ^ text_len)%r.
```

- Q: If we remove the losslessness assumptions, what would happen?
- A: Up to bad reasoning and proof that `G4.main` returns `true` with probability $1\%r / 2\%r$ would fail.

IND-CPA Security Result

- Q: Why did we start our sequence of games by switching from using the PRF F to using a true random function?
- A: We need true randomness for one-time pad argument.

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  if (u \in TRF.mp) {  
    clash_pre <- true;  
  }  
  genc_inp <- u;  
  v <$ dtext;  
  TRF.mp.[u] <- v;  
  c <- (u, x +^ v);  
  return c;  
}
```

We could have
still been using
`inps_pre`

`E0_0`

IND-CPA Security Result

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  genc_inp <- u;  
  v <$ dtext;  
  (* removed: TRF.mp.[u] <- v; *)  
  c <- (u, x +^ v);  
  return c;  
}
```

now, **v** is only used once, so we can use one-time pad technique

E0_I

IND-CPA Security Result

```
proc genc(x : text) : cipher = {  
  var u, v : text; var c : cipher;  
  u <$ dtext;  
  v <$ dtext;  
  c <- (u, v);  
  return c;  
}
```

Lets us prove
G4 returns **true**
with probability
 $\frac{1}{2^r} / \frac{1}{2^r}$

E0_N
