Security and Privacy

Singapore Airlines Software Bug Results in Breach

New Spectre-like CPU vulnerability bypasses existing defenses
The SWAPGS vulnerability can allow attackers to access contents of kernel memory addresses. Microsoft and Intel have coordinated on a mitigation.

By Lucian Constantin
CSO Senior Writer, CSO | Aug 7, 2019 3:13 AM PDT

Failure to patch two-month-old bug led to massive Equifax breach
Critical Apache Struts bug was fixed in March. In May, it bit ~143 million US consumers.

DAN GOODIN · 9/13/2017, 11:12 PM
Formal Methods aim at making this process mathematically rigorous.
Goal of formal methods: building applications that are correct.
What does “correct” mean?

A program is correct if it respects the specification:

• What is computed (functional aspects)
• How it is computed (non-functional aspects).
Why correctness matters?

An example:
DARPA HACMS (High Assurance Cyber Military Systems)

Hack-Proof Drones Possible with HACMS Technology
Is correctness easy to guarantee?
Function Add(x: int, y: int) : int
{
    r = 0;
    n = y;
    while n != 0
    {
        r = r + 1;
        n = n - 1;
    }
    return r
}
Is this code correct?

Function Add(x: int, y: int) : int
{
    r = 0;
    n = y;
    while n != 0
    {
        r = r + 1;
        n = n - 1;
    }
    return r
}
Function Add(x: int, y: int) : int
{
    r = 0;
    n = y;
    while n != 0
    {
        r = r + 1;
        n = n - 1;
    }
    return r
}
Function Add(x: int, y: int) : int
{
    r = 0;
    n = y;
    while n != 0
    {
        r = r + 1;
        n = n - 1;
    }
    return r
}

Postcondition: r = x + y
Adding the specification

Precondition: $x \geq 0$ and $y \geq 0$

Function Add($x$: int, $y$: int) : int
{
    $r = 0$;
    $n = y$;
    while $n \neq 0$
    {
        $r = r + 1$;
        $n = n - 1$;
    }
    return $r$
}

Postcondition: $r = x + y$
Does the program comply with the specification?

Precondition: \( x \geq 0 \) and \( y \geq 0 \)

Function Add(x: int, y: int) : int
{
    r = 0;
    n = y;
    while n != 0
    {
        r = r + 1;
        n = n - 1;
    }
    return r
}

Postcondition: \( r = x + y \)
Does the program comply with the specification?

Precondition: \( x \geq 0 \) and \( y \geq 0 \)

Function `Add(x: int, y: int) : int`

```java
{ 
    r = 0;
    n = y;
    while n != 0
    {
        r = r + 1;
        n = n - 1;
    }
    return r 
}
```

Postcondition: \( r = x + y \)

Fail to meet the specification
In the rest of the class

• We will focus on methods to guarantee correctness of programs with respect to security and privacy properties.

• We will address in particular some properties of security and privacy.

• We will focus on program-based methods, where the security and privacy guarantees depend on the program design.

• This is in contrast to (whole) system security and privacy, which require to consider many other aspects.
Why formal methods?

- Formal proofs can be checked by a machine, and designed with the support of a machine.
- Formal methods provide strong guarantees of software correctness.
- Formal systems usually allow us to create digital certificates that can be used to verify the trust of the software component.
- In applications that require strong security and privacy guarantees, we cannot make mistakes.
What is the recipe we will follow?

• We will look at **specific notions** of security and privacy
• We will formalize these notions, through some **formal model** useful to determine if a program satisfy this notion or not.
• We will then look at a **formal logic** which allow us to mechanize this reasoning.
• We will use the formal logic on **several examples**.
What will we look at?

• Basic methods to reason formally about whether programs meet their specification: Hoare Logic
• Adapt this method to reason about security in terms of information flow: Relational Hoare Logic
• Time permitting we will also look at quantitative information flow.
• Adapt this method to reason about security in terms of formal cryptography: Probabilistic Relational Hoare Logic
• Adapt this method to reason about data privacy in terms of differential privacy: Approximate Probabilistic Relational Hoare Logic

An introduction to relational program verification

Suggested Citation: Gilles Barthe (2015). "An introduction to relational program verification". : Vol. xx, No. xx, pp 1–l. DOI: 10.1551/XXXXXXX

Gilles Barthe

http://software.imdea.org/~gbarthe/__introrelver.pdf
Grade Break Down

• 50% Assignments
• 50% Project
Assignments (tentative)

• 1 EasyCrypt assignment to get you familiar with EasyCrypt ambient logic
• 1 EasyCrypt assignment to get you familiar with Hoare Logic
• 1 EasyCrypt assignment on Non-Interference and Relational Hoare Logic (Due in Week 6 - tentatively).
• 1 EasyCrypt assignment on Probabilistic Non-Interference
• 1 EasyCrypt assignment on Differential Privacy
EasyCrypt Assignments

• Discussions with other students about the assignment are permitted and encouraged.

• However, the solutions to the EasyCrypt assignments must be your own. **No pair or group submission is allowed.**
Academic integrity policy

The Department of Computer Science takes the academic integrity of all students seriously. In order to uphold the integrity of our programs and the university, we rely on students to behave appropriately and take responsibility for their mistakes. Please review the following pages to better understand the expectations of the department, college, and university, as well as the process of any academic misconduct matters.

- https://www.bu.edu/academics/policies/academic-conduct-code/
- https://www.bu.edu/cs/undergraduate/undergraduate-life/academic-integrity/
EasyCrypt

• Proof assistant for mechanizing proofs in the program logics we’ll study in this course
• You’ll be using EasyCrypt in the course’s assignments, and perhaps in the course project
• To date, EasyCrypt has mostly been used to mechanize proofs from theoretical cryptography
• But we’ll also consider other applications, e.g., to noninterference and differential privacy
EasyCrypt

• EasyCrypt proofs are about simple assignment-oriented programming language with while loops and random assignments
• EasyCrypt has logics supporting:
  • Reasoning about single programs
  • Reasoning about pairs of programs—relational logic
  • Reasoning in a typed higher-order logic—for general mathematics, and connecting results from other logics
EasyCrypt

• EasyCrypt proofs:
  • structured as sequences of lemmas
  • lemmas are proved using tactics, which reduce goals to zero or more subgoals
  • developed interactively using a special mode of Emacs text editor, with EasyCrypt running as subprocess
  • maybe rechecked either interactively, or in batch mode
EasyCrypt Lab Sessions

• We will have a weekly EasyCrypt lab session for showing more details about EasyCrypt than there is time for in lectures.
• Lectures will focus on theory and applications, with lab sessions focusing on realization in EasyCrypt
Final Projects

Projects can take different forms depending on the interest of each student but all the projects must have a research component.

Some examples:

• using EasyCrypt or one of its extensions to prove security and privacy of a new algorithms/protocols,
• design or implementation of a new programming language, system, or tool for security and privacy,
• development and implementation of heuristics and optimizations to speed up the verification tasks,
• investigation of new applications of relational logics or EasyCrypt.
Final Projects

We will provide some specific ideas for possible projects but other ideas may be accepted if well motivated and discussed with us.

You may work on your project alone or with others. Groups can be composed by at most two students. Each group is invited to meet with us regularly (3-4 times during the term) to check on the advancements and directions of the project.

The deadline for choosing a project is March 5th.
Questions?
Formal Logic

• We will need to reason extensively about formal specifications/requirements.
• A convenient way to express these requirements is by means of logical formulas.

\[ X = Y + 1 \text{ and } Z = X + S \]

\[ \neg X = Y \text{ or } Y < X \]

For all \( n \), \( X = n \) implies \( Y = n + 1 \)
Classical Logic Formulas: Basic Predicates

We can assume that we have some basic predicates that give us some basic formulas (for us over program’s expressions)

\[ X = Y \]

\[ X < Y \]

True

False

We can think about this as some primitive operations whose validity we are able to establish in an atomic way.
Classical Logic Formulas: Connectives

If we have a formula \( P \) we can create the formula \( \text{not } P \)

If we have a formula \( P \) and a formula \( Q \) we can create the formula \( P \text{ and } Q \)

If we have a formula \( P \) and a formula \( Q \) we can create the formula \( P \text{ or } Q \)

If we have a formula \( P \) and a formula \( Q \) we can create the formula \( P \text{ implies } Q \)
Classical Logic Formulas: Quantifiers

If we have a formula $P(x)$ which depends on the variable $x$ we can create the universally quantified formula \textit{for all} $x$, $P(x)$

If we have a formula $P(x)$ which depends on the variable $x$ we can create the existentially quantified formula \textit{exists} $x$, $P(x)$
Classical Logic: Proving formulas

When we are working with logical formulas we are in general interested in proving them true.

We could define a formal system for building proofs. This can be achieved for example by a formal system managing proof rules of the form:

\[
\begin{align*}
\text{conclusion is true} & \quad \text{assumption}_1 \text{ is true} & \quad \text{assumption}_k \text{ is true} \\
\text{conclusion is true} & \quad \text{conclusion is true}
\end{align*}
\]
Inductive proofs

For proving logical formulas true we need to build proofs.

We can inductively build proofs as trees:

Base case: a leaf

Inductive case:

\[ F_1 \text{ is true} \quad \ldots \quad F_k \text{ is true} \]

Where the assumptions of the rule have to match exactly the conclusion of the trees.
Meta-proofs

Since proofs are inductively defined objects, we can then reason about them by induction. This is useful to prove properties about the logic itself.

Some examples in formal proof systems: soundness and completeness.

Reference from programming languages:
G. Winskel - The formal semantics of programming languages (chapter 2-3)
https://www.cin.ufpe.br/~if721/intranet/TheFormalSemanticsofProgrammingLanguages.pdf
To prove that a conjunction formula $P$ and $Q$ is true, we need to show that both $P$ and $Q$ are true.

This corresponds to the following rule:

$$
\begin{array}{c}
P \text{ true} \\
\hline
P \text{ and } Q \text{ true} \\
\hline
Q \text{ true}
\end{array}
$$
Classical Logic - Proving formulas: Conjunction

To prove that a disjunction formula $P$ or $Q$ is true, it is sufficient to show that one between $P$ and $Q$ is true.

This corresponds to the following two rules:

\[
\begin{align*}
P \text{ true} & \quad P \text{ or } Q \text{ true} \\
P \text{ or } Q \text{ true} & \quad Q \text{ true} \quad P \text{ or } Q \text{ true}
\end{align*}
\]
To prove that a negation formula $\neg P$ is true, we can show that under the assumption that $P$ is true, we can conclude $False$.

This corresponds to the following rule:

\[
\begin{align*}
P & \text{ true} \\
\cdots & \\
\cdots & \\
False & \text{ true} \\
\hline
\neg P & \text{ true}
\end{align*}
\]
To prove that a negation formula not P is true, we can show that under the assumption that P is true, we can conclude False.

This corresponds to the following rule:
Notation

This way of writing can be confusing, sometime is better to just write:

\[ P \text{ true} \]
\[ . \]
\[ . \]
\[ . \]
\[ False \text{ true} \]
\[ not \ P \text{ true} \]

\[ P \]
\[ . \]
\[ . \]
\[ . \]
\[ False \]
\[ not \ P \]
Classical Logic - Proving formulas: Implication

To prove that an implication formula *P implies Q* is true, we can show that under the assumption that *P* is true, we can conclude *Q*.

This corresponds to the following rule:

\[
\begin{array}{c}
\text{[P]} \\
\cdot \\
\cdot \\
\cdot \\
\cdot \\
\hline
Q
\end{array}
\]

\[
P \text{ implies } Q
\]
Classical Logic - Proving formulas: Implication

To prove that an implication formula $P$ implies $Q$ is true, we can show that under the assumption that $P$ is true, we can conclude $Q$.

This corresponds to the following rule:

$$
\begin{array}{c}
\text{[P]} \\
\cdot \\
\cdot \\
\cdot \\
\cdot \\
Q \\
\hline
P \text{ implies } Q
\end{array}
$$

\text{P and Q} \\
\text{Q implies (P and Q)} \\
\text{P implies (Q implies (P and Q))}
\end{align*}
\]
Classical Logic - Proving formulas: Universal Quantification

To prove that a universally quantified formula \( \forall x, P(x) \) is true, we can show that under the assumption that \( x \) is an arbitrary element of the universe, we can conclude \( P(x) \).

This corresponds to the following rule:

\[
\frac{P(x)}{\forall x, P(x)}
\]
Classical Logic - Proving formulas: Universal Quantification

To prove that a universally quantified formula \( \text{for all } x, P(x) \) is true, we can show that under the assumption that \( x \) is an arbitrary element of the universe, we can conclude \( P(x) \).

This corresponds to the following rule:

\[
\frac{P(x)}{\text{for all } x, P(x)}
\]

Not very precise
Classical Logic - Proving formulas: Existential Quantification

To prove that an existentially quantified formula \( \exists x, P(x) \) is true, we can show that \( P(t) \) is true for some term \( t \) in the universe.

This corresponds to the following rule:

\[
\begin{align*}
P(t) \\
\hline
\exists x, P(x)
\end{align*}
\]
To prove that an existentially quantified formula $\exists x, P(x)$ is true, we can show that $P(t)$ is true for some term $t$ in the universe.

This corresponds to the following rule:

$$
\begin{array}{c}
P(t) \\
\hline
\exists x, P(x)
\end{array}
$$

Not very precise
Classical Logic: other rules for proving formulas

We have few other principles that we can use to prove formulas.

If we have contradictory assumptions, we can prove anything.

This corresponds to the following rule:

\[ \frac{P \text{ and } \neg P}{Q} \]
Classical Logic: other rules for proving formulas

If we have the assumption $P \implies Q$ and the assumption $P$, then we can prove $Q$.

This corresponds to the following rule:

$$
\begin{array}{c}
P \implies Q \\
\hline
P \\
\hline
Q
\end{array}
$$
If we have the assumption $P \lor Q$ and we want to prove $R$, then we can prove that $R$ follows from $P$ and that $R$ follows from $Q$.

This corresponds to the following rule:

\[
\begin{array}{ccc}
P \lor Q & \Rightarrow & R \\
\hline
[P] & [Q] & R \\
\end{array}
\]
Classical Logic: other rules for proving formulas

In classical logic we have the Law of the Excluded Middle saying that a formula P is always either true or false.

This can be formulated as the following rule

\[ P \lor \neg P \]
The negation of composed formulas can be often rewritten

\[
\begin{align*}
\neg(P \land Q) &\equiv \neg P \lor \neg Q \\
\neg(P \lor Q) &\equiv \neg P \land \neg Q \\
\neg(P \implies Q) &\equiv P \land \neg Q \\
\neg\neg P &\equiv P
\end{align*}
\]

\[
\begin{align*}
\neg\exists x, P(x) &\equiv \forall x, \neg P(x) \\
\neg\forall x, P(x) &\equiv \exists x, \neg P(x)
\end{align*}
\]

\hline
P \land \neg P \\
\hline
\text{False}
\end{align*}
\]

\[
\neg [(P \lor \neg P) \text{ implies } (P \land \neg P)]
\]
Classical Logic: proving complex fact

Classical logic can be combined with specific theories to prove more complex facts. As an example, if we combine classical logic with a theory of integers we can prove true formulas such as:

\[ \text{for all } x, y, z, \ x + y = z \text{ implies } x = z - y \]
Questions?
