## Last Time

- Deterministic Finite Automata (DFAs)
- Informal description: State diagram
- Formal description: What are they?
- Formal description: How do they compute?
- A language is regular if it is recognized by a DFA
- Intro to Nondeterministic FAs

## Nondeterminism

A Nondeterministic Finite Automaton (NFA) accepts if there exists a way to make it reach an accept state.

## Some special transitions

## $\varepsilon$-transitions <br> (don't consume a symbol)

## Example

## 0,1

[^0]
## Formal Definition of a NFA

An NFA is a 5 -tuple $M=\left(Q, \Sigma, \delta, q_{0}, F\right)$
$Q$ is the set of states
$\Sigma$ is the alphabet
$\delta: Q \times \Sigma_{\varepsilon} \rightarrow P(Q)$ is the transition function
$q_{0} \in Q$ is the start state
$F \subseteq Q$ is the set of accept states
$M$ accepts a string $w$ if there exists a path from $q_{0}$ to an accept state that can be followed by reading $w$.

## Example

$$
\begin{array}{ll}
N=\left(\boldsymbol{Q}, \boldsymbol{\Sigma}, \delta, \boldsymbol{q}_{0}, F\right) & \delta\left(\boldsymbol{q}_{\mathbf{0}}, \mathbf{0}\right)= \\
Q=\left\{\boldsymbol{q}_{\mathbf{0}} \boldsymbol{q}_{1}, \boldsymbol{q}_{2}, \boldsymbol{q}_{3}\right\} & \delta\left(\boldsymbol{q}_{\mathbf{0}}, \mathbf{1}\right)= \\
\Sigma=\left\{\begin{array}{l}
\mathbf{0}, \boldsymbol{1}\}
\end{array}\right. & \delta\left(\boldsymbol{q}_{\mathbf{1}}, \varepsilon\right)= \\
F=\left\{\boldsymbol{q}_{3}\right\} & \delta\left(\boldsymbol{q}_{2}, \mathbf{0}\right)=
\end{array}
$$

Nondeterminism

Deterministic Computation

accept or reject

Nondeterministic
Computation

Ways to think about nondeterminism

- (restricted) parallel computation
- tree of possible computations
- guessing and verifying the "right" choice

## Why study NFAs?

- Not really a realistic model of computation: Real computing devices can't really try many possibilities in parallel

## But:

- Useful tool for understanding power of DFAs/regular languages
- NFAs can be simpler than DFAs
- Lets us study "nondeterminism" as a resource (cf. P vs. NP)

## NFAs can be simpler than DFAs

A DFA that recognizes the language
$\{w \mid w$ starts with 0 and ends with 1$\}$ :

An NFA for this language:

## Equivalence of NFAs and DFAs

## Equivalence of NFAs and DFAs

Every DFA is an NFA, so NFAs are at least as powerful as DFAs

Theorem: For every NFA $N$, there is a DFA $M$ such that $L(M)=L(N)$

Corollary: A language is regular if and only if it is recognized by an NFA

> Equivalence of NFAs and DFAs (Proof) Let $N=\left(Q, \Sigma, \delta, q_{0}, F\right)$ be an NFA
> $\underline{\text { Goal: Construct DFA } M=\left(Q^{\prime}, \Sigma, \delta^{\prime}, q_{0}{ }^{\prime}, F^{\prime}\right) \text { recognizing } L(N)}$

Intuition: Run all threads of $N$ in parallel, maintaining the set of states where all threads are.

Formally: $Q^{\prime}=P(Q)$
"The Subset Construction"

NFA -> DFA Example

## Subset Construction (Formally, first attempt)

Input: NFA $N=\left(Q, \Sigma, \delta, q_{0}, F\right)$
Output: DFA $M=\left(Q^{\prime}, \Sigma, \delta^{\prime}, q_{0}{ }^{\prime}, F^{\prime}\right)$
$Q^{\prime}$
$\delta^{\prime}: Q^{\prime} \times \Sigma \rightarrow Q^{\prime}$ $\delta^{\prime}(R, \sigma)=$ for all $R \subseteq Q$ and $\sigma \in \Sigma$.

$$
\begin{aligned}
& q_{0}{ }^{\prime}= \\
& F^{\prime}=
\end{aligned}
$$

## Subset Construction (Formally, for real)

Input: NFA $N=\left(Q, \Sigma, \delta, q_{0}, F\right)$
Output: DFA $M=\left(Q^{\prime}, \Sigma, \delta^{\prime}, q_{0}{ }^{\prime}, F^{\prime}\right)$
$Q^{\prime}=P(Q)$
$\delta^{\prime}: Q^{\prime} \times \Sigma \rightarrow Q^{\prime}$
$\delta^{\prime}(R, \sigma)=\bigcup_{r \in R} \quad \delta(r, \sigma) \quad$ for all $R \subseteq Q$ and $\sigma \in \Sigma$.
$q_{0}{ }^{\prime}=\left\{q_{0}\right\}$
$F^{\prime}=\left\{R \in Q^{\prime} \mid R\right.$ contains some accept state of $\left.N\right\}$

## NFA -> DFA Example <br> 0 $\stackrel{\circ}{\circ}$ (C)

## Proving the Construction Works

Claim: For every string $w$, running $M$ on $w$ leads to state

## $\{q \in Q \mid$ There exists a computation path of $N$ on input $w$ ending at $q\}$

Proof idea: By induction on $|w|$

## Historical Note

## Subset Construction introduced in Rabin \& Scott's 1959 paper "Finite Automata and their Decision Problems"

1976 ACM Turing Award citation
For their joint paper "Finite Automata and Their Decision Problem," which introduced the idea of nondeterministic machines, which has proved to be an enormously valuable concept. Their (Scott \& Rabin) classic paper has been a continuous source of inspiration for subsequent work in this field.

## NFA -> DFA: The Catch

If $N$ is an NFA with $s$ states, how many states does the DFA obtained using the subset construction have? (In the worst case.)
a) $s$
b) $s^{2}$
c) $2^{s}$
d) None of the above

## Is this construction the best we can do?

Subset construction converts an $n$ state NFA into a $2^{n}$-state DFA

Could there be a construction that always produces, say, an $n^{2}$-state DFA?

Theorem: For every $n \geq 1$, there is a language $L_{n}$ such that

1. There is an $(n+1)$-state NFA recognizing $L_{n}$.
2. There is no DFA recognizing $L_{n}$ with fewer than $2^{n}$ states.
Conclusion: For finite automata, nondeterminism provides an exponential savings over determinism (in the worst case).

## Closure Properties

## An Analogy

In algebra, we try to identify operations which are common to many different mathematical structures

Example: The integers $\mathbb{Z}=\{\ldots-2,-1,0,1,2, \ldots\}$ are closed under

- Addition: $x+y$
- Multiplication: $x \times y$
- Negation: - $x$
- ...but NOT Division: $x / y$

We'd like to investigate similar closure properties of the class of regular languages

Regular operations on languages
Let $A, B \subseteq \Sigma^{*}$ be languages. Define

Union: $A \cup B=\{w \mid w \in A$ or $w \in B\}$

Concatenation: $A \circ B=\{x y \mid x \in A, y \in B\}$

Star: $A^{*}=$

Other operations
Let $A, B \subseteq \Sigma^{*}$ be languages. Define
Complement: $\bar{A}=\{w \mid w \notin A\}$

Intersection: $A \cap B=\{w \mid w \in A$ and $w \in B\}$

Reverse: $A^{R}=\left\{w \mid w^{R} \in A\right\}$

## Closure properties of the regular languages

Theorem: The class of regular languages is closed under all three regular operations (union, concatenation, star), as well as under complement, intersection, and reverse.
i.e., if $A$ and $B$ are regular, applying any of these operations yields a regular language

## Proving Closure Properties

## Complement

Complement: $\bar{A}=\{w \mid w \notin A\}$
Theorem: If $A$ is regular, then $\bar{A}$ is also regular Proof idea:

## Complement, Formally

Let $M=\left(Q, \Sigma, \delta, q_{0}, F\right)$ be a DFA recognizing a language $A$. Which of the following represents a DFA recognizing $\bar{A}$ ?
a) $\left(F, \Sigma, \delta, q_{0}, Q\right)$
b) $\left(Q, \Sigma, \delta, q_{0}, Q \backslash F\right)$, where $Q \backslash F$ is the set of states in $Q$ that are not in $F$
c) $\left(Q, \Sigma, \delta^{\prime}, q_{0}, F\right)$ where $\delta^{\prime}(q, s)=p$ such that $\delta(p, s)=q$
d) None of the above

[^0]:    $L(N)=$
    a) $\{w \mid w$ contains 00 or 01$\}$
    b) $\{w \mid$ the second to last symbol of $w$ is 0$\}$
    c) $\{w \mid w$ starts with 00 or 01$\}$
    d) $\{w \mid w$ ends with 001$\}$
