Polynomial-time reducibility

Definition:

A function $f: \Sigma^* \to \Sigma^*$ is polynomial-time computable if there is a polynomial-time TM M which, given as input any $w \in \Sigma^*$, halts with only $f(w)$ on its tape.

Definition:

Language A is polynomial-time reducible to language B, written

$$A \leq_{\mathrm{p}} B$$

if there is a polynomial-time computable function $f: \Sigma^* \to \Sigma^*$ such that for all strings $w \in \Sigma^*$, we have $w \in A \Leftrightarrow f(w) \in B$

NP-completeness

"The hardest languages in NP"

Definition: A language B is NP-complete if

1) $B \in \mathrm{NP}$, and

2) Every language $A \in \mathrm{NP}$ is poly-time reducible to B, i.e., $A \leq_{\mathrm{p}} B$ ("B is NP-hard")

The usual way to prove NP-completeness

Theorem:

If

1) $C \in \mathrm{NP}$, and

2) There is an NP-complete language B such that

$$B \leq_{\mathrm{p}} C$$

then C is NP-complete.

Some general reduction strategies

- Reduction by simple equivalence
  Ex. $IND - SET \leq_{\mathrm{p}} VERTEX - COVER$
  $VERTEX - COVER \leq_{\mathrm{p}} IND - SET$

- Reduction from special case to general case
  Ex. $VERTEX - COVER \leq_{\mathrm{p}} SET - COVER$
  $3SAT \leq_{\mathrm{p}} SAT$

- "Gadget" reductions
  Ex. $SAT \leq_{\mathrm{p}} 3SAT$
  $3SAT \leq_{\mathrm{p}} IND - SET$

$3SAT$ (3-CNF Satisfiability)

Definitions:

- A literal either a variable of its negation x_5 , $\overline{x_7}$
- A clause is a disjunction (OR) of literals Ex. $x_5 \vee \overline{x_7} \vee x_2$
- A 3-CNF is a conjunction (AND) of clauses where each clause contains exactly 3 literals

Ex. $C_1 \wedge C_2 \wedge \ldots \wedge C_m =$

$$(x_5 \vee \overline{x_7} \vee x_2) \wedge (\overline{x_3} \vee x_4 \vee x_1) \wedge \cdots \wedge (x_1 \vee x_1 \vee x_1)$$

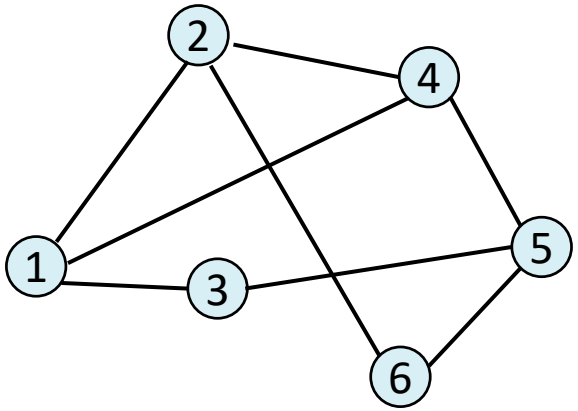
$$3SAT = \{\langle\varphi\rangle | \varphi \text{ is a satisfiable } 3 - \text{CNF}\}$$

Last time: $3SAT$ is NP-complete

Independent Set

An **independent set** in an undirected graph G is a set of vertices that includes at most one endpoint of every edge.

$$IND - SET = \{\langle G, k\rangle | G \text{ is an undirected graph containing an independent set with } \geq k \text{ vertices}\}$$



Which of the following are independent sets in this graph?

a) $\{1\}$
b) $\{1, 5\}$
c) $\{2, 3, 6\}$
d) $\{3, 4, 6\}$

Independent Set is NP-complete

1) $IND - SET \in \text{NP}$
2) Reduce $3SAT \leq_{\text{p}} IND - SET$

Proof of 1) The following gives a poly-time verifier for $IND - SET$

Certificate: Vertices $v_1, \ldots, v_k$

Verifier:

"On input $\langle G, k; v_1, \ldots, v_k \rangle$, where G is a graph, k is a natural number,

1. Check that $v_1, \ldots v_k$ are distinct vertices in G
2. Check that there are no edges between the v_i's."

Independent Set is NP-complete

1) $IND - SET \in \mathrm{NP}$
2) Reduce $3SAT \leq_{\mathrm{p}} IND - SET$

Proof of 2) The following TM computes a poly-time reduction.

"On input $\langle \varphi \rangle$, where φ is a 3CNF formula,

1. Construct graph G from φ
   - G contains 3 vertices for each clause, one for each literal.
   - Connect 3 literals in a clause in a triangle.
   - Connect every literal to each of its negations.
2. Output $\langle G, k \rangle$, where k is the number of clauses in φ."

Example of the reduction

$$\varphi = (\overline{x_1} \vee x_2 \vee x_3) \wedge (x_1 \vee \overline{x_2} \vee x_3) \wedge (\overline{x_1} \vee x_2 \vee x_3)$$

Proof of correctness for reduction

Let k = # clauses and l = # literals in φ

Correctness: φ is satisfiable iff G has an independent set of size k

$\Longrightarrow$ Given a satisfying assignment, select one true literal from each triangle. This is an independent set of size k

$\Longleftarrow$ Let S be an independent set in G of size k

- S must contain exactly one vertex in each triangle
- Set these literals to true, and set all other variables arbitrarily
- Truth assignment is consistent and all clauses are satisfied

Runtime: $O(k + l^2)$ which is polynomial in input size

Some general reduction strategies

- Reduction by simple equivalence
  Ex. $IND - SET \leq_{\mathrm{p}} VERTEX - COVER$
  $VERTEX - COVER \leq_{\mathrm{p}} IND - SET$

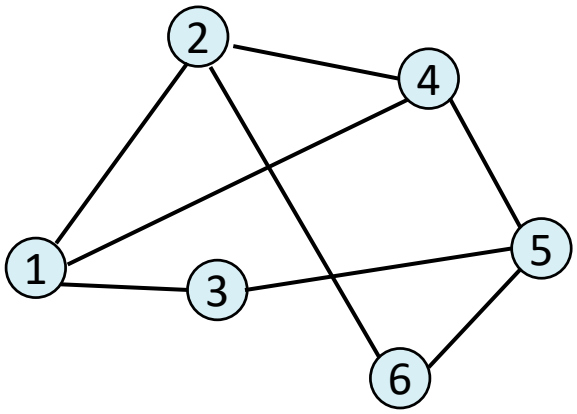
- Reduction from special case to general case
  Ex. $VERTEX - COVER \leq_{\mathrm{p}} SET - COVER$
  $3SAT \leq_{\mathrm{p}} SAT$

- "Gadget" reductions
  Ex. $SAT \leq_{\mathrm{p}} 3SAT$
  $3SAT \leq_{\mathrm{p}} IND - SET$

Vertex Cover

Given an undirected graph G, a **vertex cover** in G is a subset of nodes which includes at ***least*** one endpoint of every edge.

$VERTEX - COVER = \{\langle G, k\rangle \mid G$ is an undirected graph which has a vertex cover with $\leq k$ vertices$\}$



Which of the following are vertex covers in this graph?

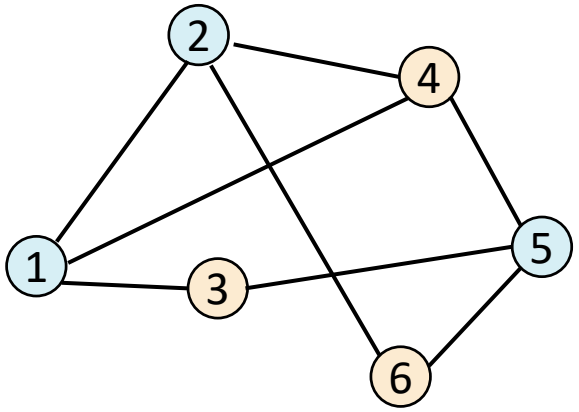
a) $\{1\}$
b) $\{1, 6\}$
c) $\{1, 2, 5\}$
d) $\{1, 2, 5, 6\}$

Independent Set and Vertex Cover

Claim. S is an independent set iff $V \setminus S$ is a vertex cover.

$\Longrightarrow$ Let S be any independent set.

- Consider an arbitrary edge (u, v).
- S is independent $\Longrightarrow u \notin S$ or $v \notin S \implies u \in V \setminus S$ or $v \in V \setminus S$.
- Thus, $V \setminus S$ covers (u, v).



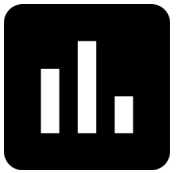
$\Longleftarrow$ Let $V \setminus S$ be any vertex cover.

- Consider two nodes $u \in S$ and $v \in S$.
- Then $(u, v) \notin E$ since $V \setminus S$ is a vertex cover.
- Thus, no two nodes in S are joined by an edge $\Longrightarrow S$ is an independent set.

INDEPENDENT SET reduces to VERTEX COVER

Theorem. IND-SET $\leq_p$ VERTEX-COVER.

What do we need to do to prove this theorem?



a) Construct a poly-time nondet. TM deciding IND-SET
b) Construct a poly-time deterministic TM deciding IND-SET
c) Construct a poly-time nondet. TM mapping instances of IND-SET to instances of VERTEX-COVER
d) Construct a poly-time deterministic TM mapping instances of IND-SET to instances of VERTEX-COVER
e) Construct a poly-time nondet. TM mapping instances of VERTEX-COVER to instances of IND-SET
f) Construct a poly-time deterministic TM mapping instances of VERTEX-COVER to instances of IND-SET

INDEPENDENT SET reduces to VERTEX COVER

Theorem. IND-SET $\leq_{\mathrm{p}}$ VERTEX-COVER.

Proof. The following TM computes the reduction.

"On input $\langle G, k \rangle$, where G is an undirected graph and k is an integer,

1. Output $\langle G, n - k \rangle$, where n is the number of nodes in G."

Correctness:

- G has an independent set of size at least k iff it has a vertex cover of size at most $n - k$.

Runtime:

- Reduction runs in linear time.

VERTEX COVER reduces to INDEPENDENT SET

Theorem. VERTEX-COVER $\leq_{\mathrm{p}}$ IND-SET

Proof. The following TM computes the reduction.

"On input $\langle G, k \rangle$, where G is an undirected graph and k is an integer,

1. Output $\langle G, n - k \rangle$, where n is the number of nodes in G."

Correctness:

- G has a vertex cover of size at most k iff it has an independent set of size at least $n - k$.

Runtime:

- Reduction runs in linear time.

A Brief Tour of Space (Complexity)

Space analysis

Space complexity of a TM (algorithm) = maximum number of tape cells it uses on a worst-case input

Formally: Let $f : \mathbb{N} \rightarrow \mathbb{N}$. A TM M runs in space $f(n)$ if on every input $w \in \Sigma^*$, M halts on w using at most $f(n)$ cells

For nondeterministic machines: Let $f : \mathbb{N} \rightarrow \mathbb{N}$. An NTM N runs in space $f(n)$ if on every input $w \in \Sigma^*$, N halts on w using at most $f(n)$ cells on every computational branch

Space complexity classes

Let $f : \mathbb{N} \rightarrow \mathbb{N}$

A language $A \in \mathrm{SPACE}(f(n))$ if there exists a basic single-tape (deterministic) TM M that

1) Decides A, and
2) Runs in space $O(f(n))$

A language $A \in \mathrm{NSPACE}(f(n))$ if there exists a single-tape nondeterministic TM N that

1) Decides A, and
2) Runs in space $O(f(n))$

Space vs. Time

$$\mathrm{TIME}\big(f(n)\big) \subseteq \mathrm{NTIME}\big(f(n)\big)$$
$$\subseteq \mathrm{SPACE}\big(f(n)\big) \subseteq \mathrm{NSPACE}\big(f(n)\big)$$

How about the opposite direction? Can low-space algorithms be simulated by low-time algorithms?

Theorem: A TM running in space $f(n)$ also runs in time $2^{O(f(n))}$

Savitch's Theorem: Deterministic vs. Nondeterministic Space

Theorem: Let f be a function with $f(n) \geq \log n$. Then $\mathrm{NSPACE}\big(f(n)\big) \subseteq \mathrm{SPACE}\left(\big(f(n)\big)^2\right)$.

Complexity class PSPACE

Definition: PSPACE is the class of languages decidable in polynomial space on a basic single-tape (deterministic) TM

$$\mathrm{PSPACE} = \bigcup_{k=1}^{\infty} \mathrm{SPACE}(n^k)$$

Definition: NPSPACE is the class of languages decidable in polynomial space on a single-tape (nondeterministic) TM

$$\mathrm{NPSPACE} = \bigcup_{k=1}^{\infty} \mathrm{NSPACE}(n^k)$$

Relationships between complexity classes

1. $\mathrm{P} \subseteq \mathrm{NP} \subseteq \mathrm{PSPACE} \subseteq \mathrm{EXP}$

since $\mathrm{SPACE}\big(f(n)\big) \subseteq \mathrm{TIME}(2^{O(f(n))})$

2. $\mathrm{P} \neq \mathrm{EXP}$

   (via time hierarchy)

Which containments in (1) are proper?

Unknown!
