

# *Sublinear Algorithms*

---

## LECTURE 4

### Last time

- Testing if a graph is connected.
- Estimating the number of connected components.
- Estimating the weight of a MST

### Today

- Limitations of sublinear-time algorithms
- Yao's Minimax Principle

*HW2 is due Thursday at 10am*

# Query Complexity

---

- **Query complexity of an algorithm** is the maximum number of queries the algorithm makes.
  - Usually expressed as a function of input length (and other parameters)
  - **Example:** the **test for sortedness** (from Lecture 2) had query complexity  $O(\log n)$  for constant  $\varepsilon$ , more precisely  $O\left(\frac{\log n}{\varepsilon}\right)$
  - **running time  $\geq$  query complexity**
- **Query complexity of a problem  $P$** , denoted  $q(P)$ , is the query complexity of the best algorithm for the problem.
  - What is  $q(\text{testing sortedness})$ ? How do we know that there is no better algorithm?

**Today:** Techniques for proving lower bounds on  $q(P)$ .

# Yao's Principle

---

A Method for Proving Lower Bounds

# *Yao's Minimax Principle*

---

Consider a computational problem on a finite domain.

- The following statements are equivalent.

## Statement 1

For any **probabilistic** algorithm  $A$  of complexity  $q$  there exists an input  $x$  s.t.  
$$\Pr_{\text{coin tosses of } A} [A(x) \text{ is wrong}] > 1/3.$$

## Statement 2

There is a distribution  $D$  on the inputs,  
s.t. for every **deterministic** algorithm of complexity  $q$ ,  
$$\Pr_{x \leftarrow D} [A(x) \text{ is wrong}] > 1/3.$$

- **Need for lower bounds**

Yao's Minimax Principle (**easy direction**): Statement 2  $\Rightarrow$  Statement 1.

# *Proof of Easy Direction of Yao's Principle*

---

- Consider a finite set of inputs  $X$  (e.g., all inputs of length  $n$ ).
  - Consider a randomized algorithm that takes an input  $x \in X$ , makes  $\leq q$  queries to  $x$  and outputs accept or reject.
  - Every randomized algorithm can be viewed as a distribution  $\mu$  on deterministic algorithms (which are decision trees).
- 
- Let  $Y$  be the set of all  $q$ -query deterministic algorithms that run on inputs in  $X$ .

# *Proof of Easy Direction of Yao's Principle*

- Consider a matrix  $M$  with
  - rows indexed by inputs  $x$  from  $X$ ,
  - columns indexed by algorithms  $y$  from  $Y$ ,
  - entry  $M(x, y) = \begin{cases} 1 & \text{if algorithm } y \text{ is correct on input } x \\ 0 & \text{if algorithm } y \text{ is wrong on input } x \end{cases}$

	$y_1$	$y_2$	...	
$x_1$	1	0		
$x_2$	1	1		
...			$\ddots$	

- Then an algorithm  $A$  is a distribution  $\mu$  over columns  $Y$  with probabilities satisfying  $\sum_{y \in Y} \mu(y) = 1$ .

# Rephrasing Statements 1 and 2 in Terms of $M$

## Statement 1

For any **probabilistic** algorithm  $A$  of complexity  $q$  there exists an input  $x$  s.t.

$$\Pr_{\text{coin tosses of } A} [A(x) \text{ is wrong}] > 1/3.$$

- For all distributions  $\mu$  over columns  $Y$ , there exists a row  $x$  s.t.

$$\Pr_{y \leftarrow \mu} [M(x, y) = 0] > 1/3.$$

## Statement 2

There is a distribution  $D$  on the inputs,

s.t. for every **deterministic** algorithm of complexity  $q$ ,

$$\Pr_{x \leftarrow D} [A(x) \text{ is wrong}] > 1/3.$$

- There is a distribution  $D$  over rows  $X$ , s.t. for all columns  $y$ ,

$$\Pr_{x \leftarrow D} [M(x, y) = 0] > 1/3.$$

# Statement 2 $\Rightarrow$ Statement 1

- Suppose there is a distribution  $D$  over  $X$ , s.t. for all columns  $y$ ,

$$\Pr_{x \leftarrow D} [M(x, y) = 0] > 1/3.$$

- Then for **all** distributions  $\mu$  over  $Y$ ,

$$\Pr_{\substack{x \leftarrow D \\ y \leftarrow \mu}} [M(x, y) = 0] > 1/3.$$

- Then for **all** distributions  $\mu$  over  $Y$ , there exists a row  $x$ ,

$$\Pr_{y \leftarrow \mu} [M(x, y) = 0] > 1/3.$$

	$y_1$	$y_2$	...	
$x_1$	1	0		
$x_2$	1	1		
...			$\ddots$	

# Yao's Principle (Easy Direction)

## Statement 1

For any **probabilistic** algorithm  $A$  of complexity  $q$  there exists an input  $x$  s.t.

$$\Pr_{\text{coin tosses of } A} [A(x) \text{ is wrong}] > 1/3.$$

## Statement 2

There is a distribution  $D$  on the inputs,

s.t. for every **deterministic** algorithm of complexity  $q$ ,

$$\Pr_{x \leftarrow D} [A(x) \text{ is wrong}] > 1/3.$$

- Need for lower bounds

Yao's Minimax Principle (easy direction): Statement 2  $\Rightarrow$  Statement 1.

NOTE: Also applies to restricted algorithms

- 1-sided error tests
- nonadaptive tests

# *Yao's Minimax Principle as a game*

---

**Players:** Evil algorithms designer AI and poor lower bound prover Lola.

## Game1

Move 1. AI selects a q-query **randomized** algorithm A for the problem.

Move 2. Lola selects an input on which A errs with largest probability.

## Game2

Move 1. Lola selects a distribution on inputs.

Move 2. AI selects a q-query **deterministic** algorithm with as large probability of success on Lola's distribution as possible.

# Toy Example: a Lower Bound for Testing 0\*

Input: string of  $n$  bits

Question: Does the string contain only 0's or is it  $\varepsilon$ -far from the all-0 string?

Claim. Any algorithm needs  $\Omega(1/\varepsilon)$  queries to answer this question w.p.  $\geq 2/3$ .

Proof: By Yao's Minimax Principle, enough to prove Statement 2.

## Distribution $D$ on $n$ -bit strings

- Divide the input string into  $1/\varepsilon$  blocks of size  $\varepsilon n$ .
- Let  $y_i$  be the string where the  $i$ th block is 1s and remaining bits are 0.
- Distribution  $D$  gives the all-0 string w.p.  $1/2$  and  $y_i$  with w.p.  $1/2$ , where  $i$  is chosen uniformly at random from  $1, \dots, 1/\varepsilon$ .

# A Lower Bound for Testing $0^*$

**Claim.** Any  $\varepsilon$ -test for  $0^*$  needs  $\Omega(1/\varepsilon)$  queries.

**Proof (continued):** Now fix a deterministic tester A making  $q < 1/3\varepsilon$  queries.

1. A must accept if all answers are 0. Otherwise, it would be wrong on all-0 string, that is, with probability  $1/2$  with respect to  $D$ .
2. Let  $i_1, \dots, i_q$  be the positions A queries when it sees only 0s. The test can choose its queries based on previous answers. However, since all these answers are 0 and since A is deterministic, the query positions are fixed.
  - At least  $1/\varepsilon - q > \frac{2}{3\varepsilon}$  of the blocks do not hold any queried indices.
  - Therefore, A accepts  $> 2/3$  of the inputs  $y_i$ . Thus, it is wrong with probability  $> \frac{2}{3\varepsilon} \cdot \frac{\varepsilon}{2} = \frac{1}{3}$

Context: [Alon Krivelevich Newman Szegedy 99]

Every regular language can be tested in  $O(1/\varepsilon \text{ polylog } 1/\varepsilon)$  time

# A Lower Bound for Testing Sortedness

Input: a list of  $n$  numbers  $x_1, x_2, \dots, x_n$

Question: Is the list **sorted** or  $\epsilon$ -far from sorted?

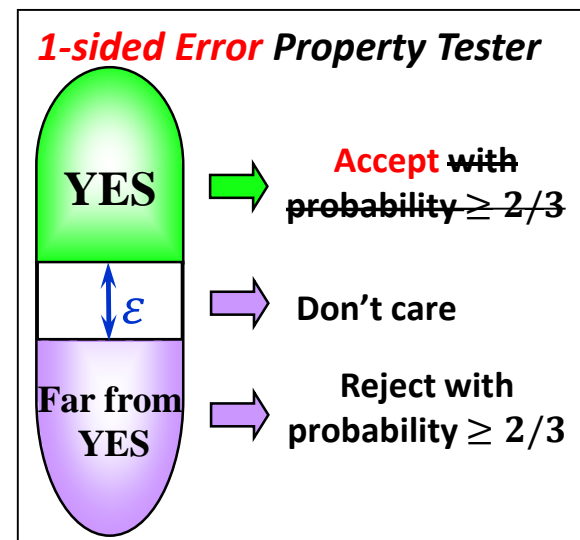

Already saw: two different  $O((\log n)/\epsilon)$  time testers.

Known [Ergün Kannan Kumar Rubinfeld Viswanathan 98, Fischer 01]:

$\Omega(\log n)$  queries are required for all constant  $\epsilon \leq 1/2$

Today:  $\Omega(\log n)$  queries are required for all constant  $\epsilon \leq 1/2$   
for every **1-sided error nonadaptive** test.

- A test has **1-sided error** if it always accepts all YES instances.
- A test is **nonadaptive** if its queries do not depend on answers to previous queries.

# *1-Sided Error Tests Must Catch “Mistakes”*

- A pair  $(i, j)$  is **violated** if  $i < j$  but  $x_i > x_j$

Claim. A 1-sided error test can reject only if it finds a violated pair.

**Proof:** Every sorted partial list can be extended to a sorted list.

1	?	?	4	...	7	?	?	9
---	---	---	---	-----	---	---	---	---

# Yao's Principle Game [Jha]

Lola's distribution is uniform over the following  $\log n$  lists:

Claim 1. All lists above are  $1/2$ -far from sorted.

Claim 2. Every pair  $(i, j)$  is violated in exactly one list above.

# Yao's Principle Game: Al's Move

Al picks a set  $Q = \{a_1, a_2, \dots, a_{|Q|}\}$  of positions to query.

- His test must be correct, i.e., must find a violated pair with probability  $\geq 2/3$  when input is picked according to Lola's distribution.
- $Q$  contains a violated pair  $\Leftrightarrow (a_i, a_{i+1})$  is violated for some  $i$

$$\Pr_{\ell \leftarrow \text{Lola's distribution}} [(a_i, a_{i+1}) \text{ for some } i \text{ is violated in list } \ell] \leq \frac{|Q| - 1}{\log n}$$

- If  $|Q| \leq \frac{2}{3} \log n$  then this probability is  $< \frac{2}{3}$

By the Union Bound

- So,  $|Q| = \Omega(\log n)$
- By Yao's Minimax Principle, every randomized 1-sided error nonadaptive test for sortedness must make  $\Omega(\log n)$  queries. ✓

# Testing Monotonicity of functions on Hypercube

---

Non-adaptive 1-sided error  
Lower Bound

# Boolean Functions $f : \{0, 1\}^n \rightarrow \{0, 1\}$

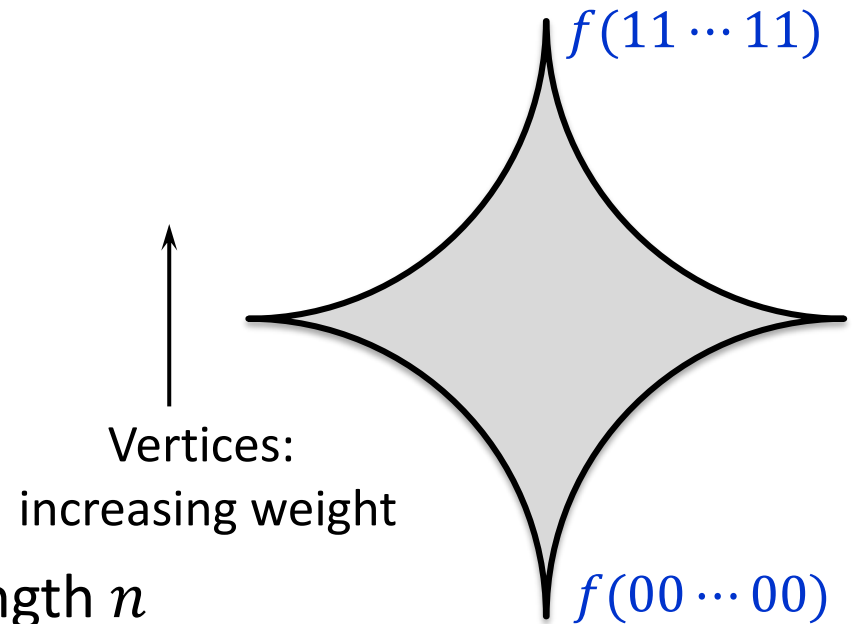

Graph representation:  
 $n$ -dimensional hypercube

- **vertices:** bit strings of length  $n$
  - **edges:**  $(x, y)$  is an edge if  $y$  can be obtained from  $x$  by increasing one bit from 0 to 1
- |     |        |
|-----|--------|
| $x$ | 001001 |
| $y$ | 011001 |
- each vertex  $x$  is labeled with  $f(x)$

# Boolean Functions $f : \{0, 1\}^n \rightarrow \{0, 1\}$

Graph representation:  
 $n$ -dimensional hypercube

- $2^n$  **vertices**: bit strings of length  $n$
- $2^{n-1}n$  **edges**:  $(x, y)$  is an edge if  $y$  can be obtained from  $x$  by increasing one bit from 0 to 1

$x$	001001
$y$	011001

- each vertex  $x$  is labeled with  $f(x)$

# Monotonicity of Functions

[Goldreich Goldwasser Lehman Ron Samorodnitsky,  
Dodis Goldreich Lehman Raskhodnikova Ron Samorodnitsky  
Fischer Lehman Newman Raskhodnikova Rubinfeld Samorodnitsky]

- A function  $f : \{0,1\}^n \rightarrow \{0,1\}$  is **monotone** if increasing a bit of  $x$  does not decrease  $f(x)$ .

- Is  $f$  monotone or  $\varepsilon$ -far from monotone ( $f$  has to change on many points to become monotone)?
  - Edge  $x \rightarrow y$  is **violated** by  $f$  if  $f(x) > f(y)$ .

Time:

- $O(n/\varepsilon)$ , logarithmic in the size of the input,  $2^n$
- $\Omega(\sqrt{n}/\varepsilon)$  for 1-sided error, nonadaptive tests
- Advanced techniques:  $\Theta(\sqrt{n}/\varepsilon^2)$  for nonadaptive tests,  $\Omega(\sqrt[3]{n})$

[Khot Minzer Safra 15, Chen De Servidio Tang 15, Chen Waingarten Xie 17]

# Hypercube 1-sided Error Lower Bound

**Lemma** [Fischer Lehman Newman Raskhodnikova Rubinfeld Samorodnitsky]

Every **1-sided error nonadaptive** test for monotonicity of functions  $f : \{0,1\}^n \rightarrow \{0,1\}$  requires  $\Omega(\sqrt{n})$  queries.

- 1-sided error test must accept if no violated pair is uncovered.

Violated pair: 

- A distribution on far from monotone functions suffices.

# Hypercube 1-sided Error Lower Bound

- Hard distribution: pick coordinate  $i$  at random and output  $f_i$ .

# The Fraction of Nodes in Middle Layers

## Hoeffding Bound

Let  $Y_1, \dots, Y_s$  be independently distributed random variables in  $[0,1]$ .

Let  $Y = \frac{1}{s} \cdot \sum_{i=1}^s Y_i$  (called *sample mean*). Then  $\Pr[|Y - E[Y]| \geq \varepsilon] \leq 2e^{-2s\varepsilon^2}$ .

$E[Y] =$

$\varepsilon =$

# Hypercube 1-sided Error Lower Bound

- Hard distribution: pick coordinate  $i$  at random and output  $f_i$ .

## Analysis

- Edges from  $(x_1, \dots, x_{i-1}, 0, x_{i+1}, \dots, x_n)$  to  $(x_1, \dots, x_{i-1}, 1, x_{i+1}, \dots, x_n)$  are violated if both endpoints are in the middle.
- The middle contains a constant fraction of vertices.
- All  $n$  functions are  $\epsilon$ -far from monotone for some constant  $\epsilon$ .

# Hypercube 1-sided Error Lower Bound

- How many functions does a set of  $q$  queries expose?

- queries

	$i$	$j$	$k$
$x$	1	1	0
$y$	0	0	1

Pair  $(x, y)$   
can expose only  
functions  $f_i, f_j$  and  $f_k$

## Naive Analysis

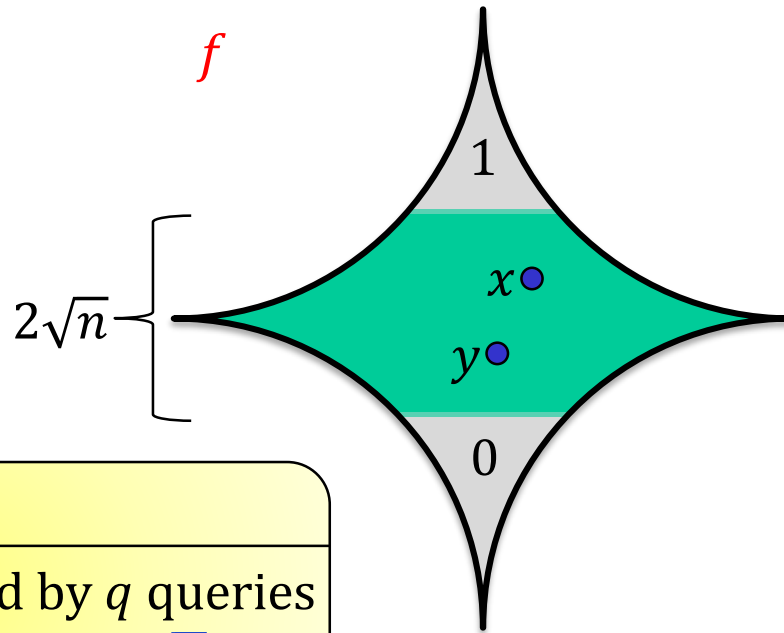

# functions exposed by  $q$  queries  
 $\leq q^2 \cdot 2\sqrt{n}$

# functions that a query pair  $(x, y)$  exposes  
 $\leq$  # coordinates on which  $x$  and  $y$  differ  
 $\leq 2\sqrt{n}$

Only pairs of queries in the Green Band can be violated  $\Rightarrow$  disagreements  $\leq 2\sqrt{n}$

# Hypercube 1-sided Error Lower Bound

- How many functions does a set of  $q$  queries expose?

- queries

	$i$	$j$	$k$
$x$	1	1	0
$y$	0	0	1

Pair  $(x, y)$   
can expose only  
functions  $f_i, f_j$  and  $f_k$

## Claim

# functions exposed by  $q$  queries  
 $\leq (q - 1) \cdot 2\sqrt{n}$

# functions that a query pair  $(x, y)$  exposes  
 $\leq$  # coordinates on which  $x$  and  $y$  differ  
 $\leq 2\sqrt{n}$

Only pairs of queries in the Green Band can be violated  $\Rightarrow$  disagreements  $\leq 2\sqrt{n}$

# Hypercube 1-sided Error Lower Bound

- How many functions does a set of  $q$  queries expose?

## Claim

# functions exposed by  $q$  queries

$$\leq (q - 1) \cdot 2\sqrt{n}$$

sufficient to consider adjacent vertices in a minimum spanning forest on the query set

$(x, y)$  a violation pair

Some adjacent pair of vertices in a minimum spanning forest on the query set is also violated

# Hypercube 1-sided Error Lower Bound

- How many functions does a set of  $q$  queries expose?

## Claim

# functions exposed by  $q$  queries  
 $\leq (q - 1) \cdot 2\sqrt{n}$

## Claim

Every deterministic test that makes a set  $Q$  of  $q$  queries (in the middle) succeeds with probability  $O\left(\frac{q}{\sqrt{n}}\right)$  on our distribution.
