#### Approximate Max-Cut

[Goldreich Goldwasser Ron 98]

# Max Cut in Dense Graphs

---

- Let  $G = (V, E)$  be an undirected  $n$ -node graph.
- Let  $(V_1, V_2)$  be a partition of  $V$ .

$e(V_1, V_2)$  = set of edges crossing the cut

# Max Cut in Dense Graphs

- Let  $G = (V, E)$  be an undirected  $n$ -node graph.

- Let  $(V_1, V_2)$  be a partition of  $V$ .

$e(V_1, V_2)$  = set of edges crossing the cut

- The edge density of the cut, denoted  $\mu(V_1, V_2)$ , is  $\frac{|e(V_1, V_2)|}{n^2}$ .

- The edge density of the largest cut in  $G$  is

$$\mu(G) = \max_{(V_1, V_2)} \mu(V_1, V_2)$$

# Approximate Max-Cut Problem

---

**Input:** parameter  $\varepsilon$ , access to undirected graph  $G = (V, E)$  represented by  $n \times n$  adjacency matrix.

**Goal 1:** Output an estimate  $\hat{\mu}$  such that:

$$\Pr[|\hat{\mu} - \mu(G)| \leq \varepsilon] \geq 2/3$$

- **[GGR98]:**  $\text{poly}\left(\frac{1}{\varepsilon}\right)$  queries and  $O\left(2^{\text{poly}\left(\frac{1}{\varepsilon}\right)}\right)$  time

**Goal 2:** Output a partition  $(V_1, V_2)$  with edge density

$$\mu(V_1, V_2) \geq \mu(G) - \varepsilon$$

with probability at least  $2/3$ .

- **[GGR98]:**  $O\left(2^{\text{poly}\left(\frac{1}{\varepsilon}\right)} + n \cdot \text{poly}\left(\frac{1}{\varepsilon}\right)\right)$  time

# Greedy Partitioning

---

- Suppose we have a partition  $(L_1, L_2)$  of  $L \subset V$ .
- In which part should we place a new node  $v$  to maximize edge density?
- Let  $\Gamma(v, U)$  be the number of neighbors of  $v$  in  $U$ .
- **Greedy:** If  $\Gamma(v, L_1) \leq \Gamma(v, L_2)$ , place  $v$  in  $L_1$ ; otherwise, place it in  $L_2$ .

# Main Idea

- Partition  $V$  into sets  $V^{(i)}$  of (almost) equal size. Assume they are of equal size.
- For each set  $V^{(i)}$ , sample a learning set  $L^{(i)}$  from the vertices not in  $V^{(i)}$ .
- Consider all partitions of  $L^{(i)}$ .

A partition of  $L^{(i)}$  induces a partition of  $V^{(i)}$   
via the greedy rule

A partition sequence  $\pi(L) = \left( \left( L_1^{(1)}, L_2^{(1)} \right), \dots, \left( L_1^{(t)}, L_2^{(t)} \right) \right)$   
induces a partition of  $V$

- Consider all such partitions of  $V$  and pick the best.

# Preliminary Max-Cut Approximation Algorithm

Algorithm (Input:  $\varepsilon, n$ ; query access to adjacency matrix of  $G=(V,E)$ )

1. Partition  $V$  into  $t = 4/\varepsilon$  sets  $V^{(1)}, V^{(2)}, \dots, V^{(t)}$  of (almost) equal size.
2. For each  $i \in [t]$ , select a set  $L^{(i)}$  of size  $\ell = \frac{1}{\varepsilon^2} \cdot \log \frac{1}{\varepsilon}$  u.i.r. from  $V \setminus V^{(i)}$ .  
Let  $L = (L^{(1)}, L^{(2)}, \dots, L^{(t)})$ .
3. For each partition sequence  $\pi(L) = \left( (L_1^{(1)}, L_2^{(1)}), \dots, (L_1^{(t)}, L_2^{(t)}) \right)$
4. For each  $i \in [t]$
5. Partition  $V^{(i)}$  into  $(V_1^{(i)}, V_2^{(i)})$  using the greedy rule:  
place  $v$  in  $V_1^{(i)}$  iff  $\Gamma(v, L_1) \leq \Gamma(v, L_2)$ .
6. Let  $V_1^\pi = \cup_i V_1^{(i)}$  and  $V_2^\pi = \cup_i V_2^{(i)}$ ; calculate  $\mu(V_1^\pi, V_2^\pi)$ .
7. Output the cut  $(V_1^\pi, V_2^\pi)$  with the largest density.

- Number of partition sequences:  $(2^\ell)^t = 2^{\text{poly}(\frac{1}{\varepsilon})}$

- Running time:  $n^2 \cdot 2^{\text{poly}(\frac{1}{\varepsilon})}$

$O(n^2)$  time for calculating each density

# Correctness of Max-Cut Approximation

## Correctness Theorem

Let  $(H_1, H_2)$  be a partition of  $V$ .

Think:  $(H_1, H_2)$  is a max-cut

w. p.  $\geq 5/6$  over the choice of  $L$ , some partition sequence  $\pi(L)$

induces a partition  $(V_1^\pi, V_2^\pi)$  of  $V$  s. t.  $\mu(V_1^\pi, V_2^\pi) \geq \mu(H_1, H_2) - 3\epsilon/4$

**Main Proof Idea:** Use a hybrid argument.

- $(H_1^{(0)}, H_2^{(0)}) = (H_1, H_2)$
- For  $i \in [t]$ , partition  $(H_1^{(i)}, H_2^{(i)})$  is obtained from  $(H_1^{(i-1)}, H_2^{(i-1)})$  by repartitioning  $V^{(i)}$  into  $(V_1^{(i)}, V_2^{(i)})$ , the best out of all partitions induced by a partition of  $L^{(i)}$ .
- We will show that when we go from one hybrid to the next, the density does not drop too much (w.h.p.)

$i$ -th hybrid partition  $(H_1^{(i)}, H_2^{(i)})$

# Correctness of Max-Cut Approximation

## Correctness Theorem

Let  $(H_1, H_2)$  be a partition of  $V$ .

W. p.  $\geq 5/6$  over the choice of  $L$ , some partition sequence  $\pi(L)$

induces a partition  $(V_1^\pi, V_2^\pi)$  of  $V$  s. t.  $\mu(V_1^\pi, V_2^\pi) \geq \mu(H_1, H_2) - 3\varepsilon/4$

**Proof:** Consider  $i \in [t]$  and fix learning sets  $L^{(1)}, \dots, L^{(i-1)}$ .

- Let  $A_i$  be the event that  $\mu(H_1^{(i)}, H_2^{(i)}) \geq \mu(H_1^{(i-1)}, H_2^{(i-1)}) - \frac{3\varepsilon}{4t}$

## Main Lemma

$\Pr[A_i] \geq 1 - \frac{1}{6t}$ , where the probability is taken over the choice of  $L^{(i)}$ .

- Then, by a union bound,

$$\Pr \left[ \bigcup_i \overline{A_i} \right] \leq t \cdot \frac{1}{6t} = \frac{1}{6}$$

# Big Picture

When we go from hybrid  $i - 1$  to hybrid  $i$ , only nodes in  $V^{(i)}$  get repartitioned.

- Let  $R_1 = V \setminus V^{(i)} \cap H_1^{(i-1)}$  and  $R_2 = V \setminus V^{(i)} \cap H_2^{(i-1)}$
- Let  $L_1^{(i)} = L^{(i)} \cap H_1^{(i-1)}$  and  $L_2^{(i)} = L^{(i)} \cap H_2^{(i-1)}$

# Proof of Main Lemma

- A node  $v$  is **good** w.r.t.  $(L_1^{(i)}, L_2^{(i)})$  if  $\left| \frac{\Gamma(v, L_j^{(i)})}{\ell} - \frac{\Gamma(v, R_j)}{n} \right| \leq \frac{\varepsilon}{8} \forall j \in \{1,2\}$
- Learning set  $L^{(i)}$  is **good** for  $(R_1, R_2)$  if  $\leq \frac{\varepsilon}{4}$  fraction of nodes in  $V^{(i)}$  are bad

## Claim 1

The probability that all  $t$  learning sets are good is at least  $5/6$ .

- A node  $v$  is **balanced** w.r.t.  $(R_1, R_2)$  if  $\left| \frac{\Gamma(v, R_1)}{n} - \frac{\Gamma(v, R_2)}{n} \right| \leq \frac{\varepsilon}{4}$

## Observation

If all learning sets are good, all good unbalanced nodes are placed correctly.

**Proof:** Suppose w.l.o.g. that  $\Gamma(v, R_1) \leq \Gamma(v, R_2)$  for a good unbalanced node  $v$

$$\frac{\varepsilon}{4} < \frac{\Gamma(v, R_2)}{n} - \frac{\Gamma(v, R_1)}{n} \leq \left( \frac{\Gamma(v, L_2^{(i)})}{n} + \frac{\varepsilon}{8} \right) - \left( \frac{\Gamma(v, L_1^{(i)})}{n} - \frac{\varepsilon}{8} \right)$$

So,  $\Gamma(v, L_1^{(i)}) < \Gamma(v, L_2^{(i)})$ , and  $v$  is placed correctly.

# Density Loss from Repartitioning $V^{(i)}$

when  $(L_1^{(i)}, L_2^{(i)})$  is good

Type of cut-edges	Number of edges lost
Incident to good unbalanced nodes	
Incident to bad unbalanced nodes	
Incident to balanced nodes	
Between nodes of $V^{(i)}$	

Total:  $\frac{3\varepsilon}{4t} \cdot n^2$

- Recall:  $A_i$  is the event that  $\mu(H_1^{(i)}, H_2^{(i)}) \geq \mu(H_1^{(i-1)}, H_2^{(i-1)}) - \frac{3\varepsilon}{4t}$
- When  $(L_1^{(i)}, L_2^{(i)})$  is good,  $A_i$  occurs.
- It remains to show that w.p.  $\geq 5/6$  all learning sets are good.

# Probability of Good Learning Sets

- A node  $v$  is **good** w.r.t.  $(L_1^{(i)}, L_2^{(i)})$  if  $\left| \frac{\Gamma(v, L_j^{(i)})}{\ell} - \frac{\Gamma(v, R_j)}{n} \right| \leq \frac{\varepsilon}{8} \quad \forall j \in \{1,2\}$
- Learning set  $L^{(i)}$  is **good** for  $(R_1, R_2)$  if  $\leq \frac{\varepsilon}{4}$  fraction of nodes in  $V^{(i)}$  are bad

## Claim 1

The probability that all  $t$  learning sets are good is at least  $5/6$ .

**Proof:** It suffices to prove that  $\Pr[L^{(i)} \text{ is bad}] \leq \frac{1}{6t}$

- Fix  $v \in V^{(i)}$
- Let  $L^{(i)} = \{v_1, \dots, v_\ell\}$ . Recall that it is chosen u.i.r. from  $V \setminus V^{(i)}$

$$X_j^k = \begin{cases} 1, & \text{if } v_k \text{ is a neighbor of } v \text{ in } R_j \\ 0, & \text{otherwise} \end{cases} \quad \forall j \in \{1,2\}$$

$$X_j = \sum_{k \in [\ell]} X_j^k = \Gamma(v, L_j^{(i)})$$

$$\mathbb{E}[X_j] = \sum_{k \in [\ell]} \mathbb{E}[X_j^k] = \ell \cdot \frac{1}{n} \Gamma(v, R_j)$$

- Use Hoeffding Bound.

# Improved Max-Cut Approximation Algorithm

Algorithm (Input:  $\varepsilon, n$ ; query access to adjacency matrix of  $G=(V,E)$ )

1. Partition  $V$  into  $t = 4/\varepsilon$  sets  $V^{(1)}, V^{(2)}, \dots, V^{(t)}$  of (almost) equal size.
2. For each  $i \in [t]$ , select a set  $L^{(i)}$  of size  $\ell = \frac{1}{\varepsilon^2} \cdot \log \frac{1}{\varepsilon}$  u.i.r. from  $V \setminus V^{(i)}$ .  
Let  $L = (L^{(1)}, L^{(2)}, \dots, L^{(t)})$ .
3. Select u.i.r.  $S$  of size  $m = \frac{t\ell}{\varepsilon^2}$
4. For each partition sequence  $\pi(L) = \left( (L_1^{(1)}, L_2^{(1)}), \dots, (L_1^{(t)}, L_2^{(t)}) \right)$
5. For each  $i \in [t]$
6. Partition  $S^{(i)}$  into  $(S_1^{(i)}, S_2^{(i)})$  using the greedy rule:  
add  $v$  to  $S_1^{(i)}$  iff  $\Gamma(v, L_1) \leq \Gamma(v, L_2)$ .
7. Let  $S_1^\pi = \cup_i S_1^{(i)}$  and  $S_2^\pi = \cup_i S_2^{(i)}$ ; calculate
 
$$\mu'(S_1^\pi, S_2^\pi) = \frac{|\{k: \{s_{2k-1}, s_{2k}\} \in e(S_1^\pi, S_2^\pi)\}|}{m/2}$$
8. Output  $\max_\pi \mu'(S_1^\pi, S_2^\pi)$

- We can also output the cut of  $V$  induced by  $\pi$  with  $\max \mu'$
